POWER HOUSE

A semi-monthly newspaper devoted to the Generation, Transmission, and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Published by The MacLean Publishing Company, Limited, 143-153 University Ave., Toronto

MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1103 Union Trust Bldg.

Vol. XIII.—No. 1. Publication Office, Toronto—January 5, 1920 Published Semi-Monthly Canada, $2; U.S. $2.50 a year

You can patch up holes in your Boiler Furnace Lining

in a Jiffy

with

PYRO-PUTTY TRADE MARK REG U.S. PAT OFF

FIRE BRICK IN PUTTY FORM

The World's Best Furnace Lining Material

PYRO-PUTTY comes to you in a stiff, moist, pliable, "ready to use" condition. PYRO-PUTTY enables unskilled labor to make furnace lining repairs in less time and at less expense than would be possible with standard fire bricks. Simply clean out the breaks in the walls, pound in PYRO-PUTTY with a mallet, smooth it off with a trowel and you'll have a patch that will out-wear the rest of the furnace lining.

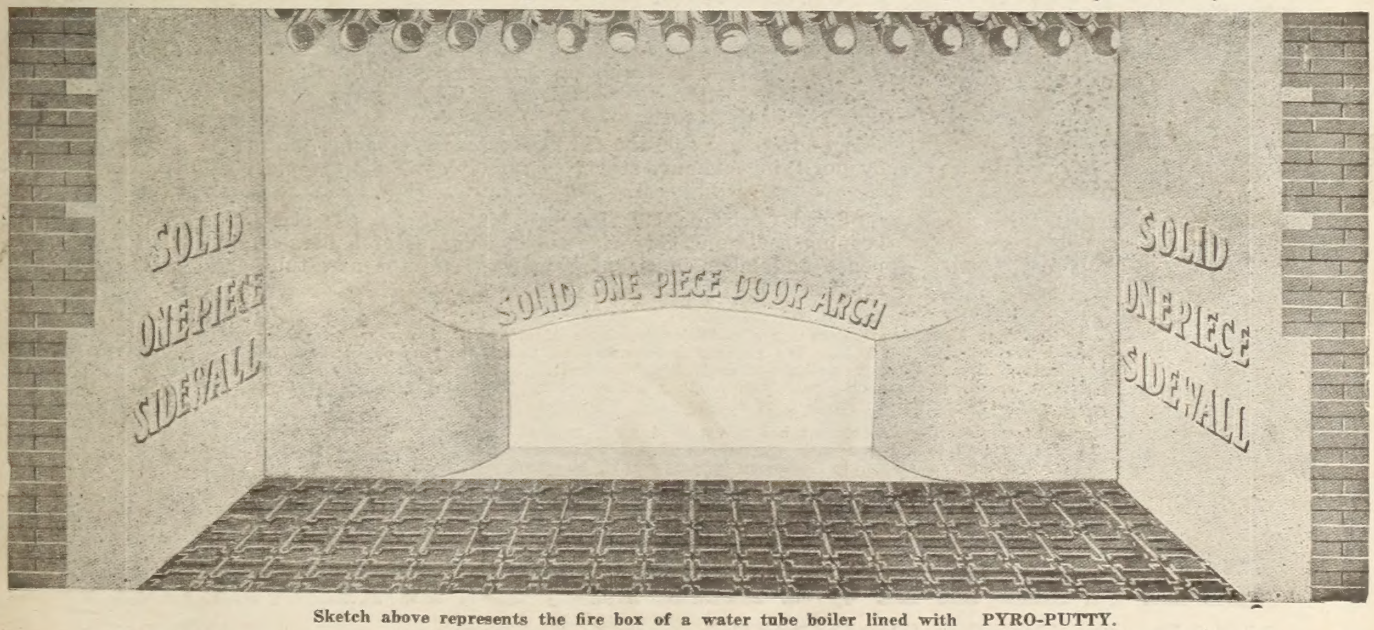
Pyro-Putty is far more durable than standard Fire Bricks for making New Furnace Linings

PYRO-PUTTY should be used, in preference to standard fire bricks, for making complete furnace linings because it is far more durable. And furnaces lined with PYRO-PUTTY are both efficient and economical because there are no joints to let the hot air out or the cold air in.

PYRO-PUTTY is put up in 700-lb. barrels, a barrel being equivalent to 100 standard fire brick. Sketch below represents the fire box of water tube boiler lined with PYRO-PUTTY. Compare it with your own fire box linings—then

ORDER A FEW BARRELS OF PYRO-PUTTY NOW!

"A few barrels of Pyro-Putty should be part of the emergency equipment of every steam power plant"



Sketch above represents the fire box of a water tube boiler lined with PYRO-PUTTY.

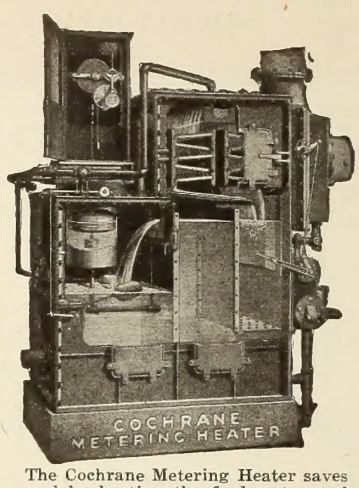
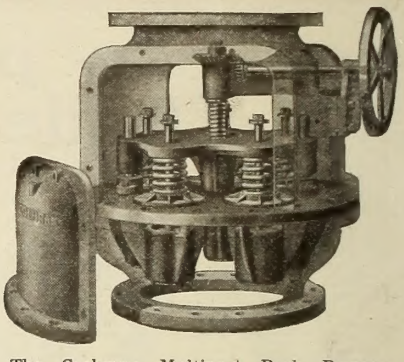
COCHRANE
COAL SAVERS

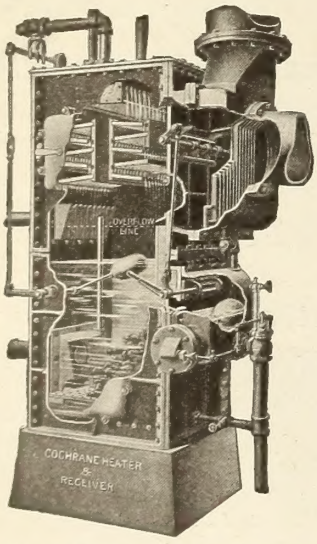
The Cochrane Oil Separator saves coal by rendering the exhaust steam useful for heating, drying and other purposes.



The Cochrane Metering Heater saves coal by heating the feed water and helps save coal by telling whether or not the plant is being operated economically.



The Cochrane Multiport Back Pressure Valve saves coal by preventing leakage of exhaust steam and by making it easy to adjust the back pressure whenever desired. The Cochrane Oil Separator saves coal by rendering the exhaust steam useful for heating, drying and other purposes.



The Cochrane Open Feed Water Heater saves coal by utilizing exhaust steam to heat the feed water; 1% saving for each 11° F. rise.

Canada is Saving Many Thousand Tons
of Coal Per Year by Using Cochrane Heaters

Here are the figures:

The **horsepower** of Cochrane Heaters in use is about 10,000,000 boiler horsepower.

The corresponding amount of **coal burned** is 35,000,000 lb. per hour.

Considering an average of 10 hours' operation per day, 300 days per year (many heaters run 24 hours per day, 365 days per year), this amounts to 105,000,000,000 lb. of coal per year, or 50,000,000 tons, worth at $5.00 per ton, **$250,000,000.**

The saving due to the use of **Cochrane Heaters** is 1% to each 11° F. rise in temperature. On the average, the water is raised from 100° F. to 210° F. using steam at atmospheric pressure, 10% or a saving of 10%. Cochrane Heaters are thus saving **about $25,000,000** per year, which is vastly more than the heaters cost.

In addition, Cochrane Oil Separators are saving millions of tons of coal by **purifying exhaust steam** so that it can take the place of live steam in heating and drying coils, low pressure turbines and industrial processes.

Sorge-Cochrane Hot Process Water Softeners are saving millions by **keeping scale and corrosive substances out of boilers** and thus saving expense and labor in cleaning boilers, and for new tubes and other boiler repairs.

Cochrane Metering Heaters are also telling hundreds of **steam-plant owners,** managers and operators how much **they are gaining in economy** by using different coals, different methods of firing, different methods of controlling the draft, stopping up air leaks in boiler settings, cleaning soot and scale from heating surface, etc. The total gains realized in this manner often amount to 25% or more.

Our engineering department has given hard study to fuel economy for over 25 years. It will be glad to aid you with suggestions if you will describe your present boiler feed water heating, softening, or metering arrangements, the amount of exhaust steam you have available and what you are using it for.

Ask for a book on "The Profitable Utilization of Exhaust Steam."

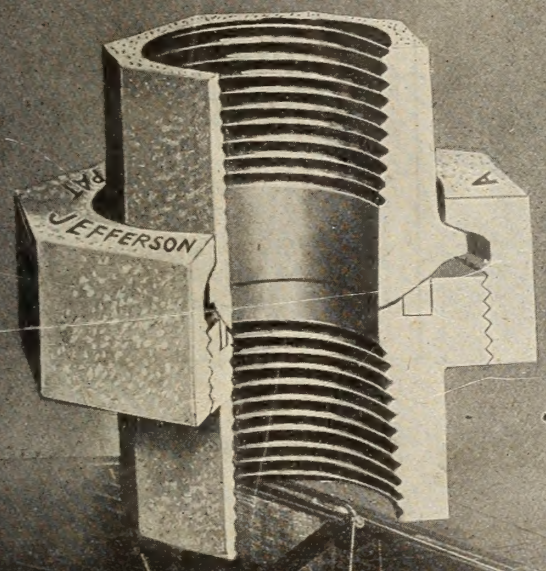
JEFFERSON

"Look for the Name on the Nut"



The Power behind the Hoist

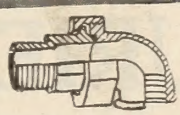
HOISTS must make their long heavy pulls without faltering, but with absolute certainty. The power behind the hoist must be sure and certain—steam pressure in the great cylinders must be constant and steady.

JEFFERSON UNIONS play a mighty part in the safe operation of hoists and other machinery. Their uniform perfection insures against breakdowns and dangerous steam losses.

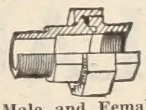
The name "JEFFERSON" protects you from the "just-as-good" variety of unions which might involve a costly shutdown or loss of life at a critical moment.

Ask your jobber about JEFFERSON'S
Also write to-day for our Catalog "UNIONS."

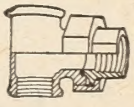
The Jefferson Union Co.
Lexington, Mass.



Union Elbow, an economizer of the most pronounced type. Also made all female.



Male and Female Union. Takes the place of an all-female union and a nipple. Makes a short connection.



Union Tee, with union on the outlet. Made also with male end on outlet.

The New "Emco" A332
Stop and Waste Cock

A "Two in one Fitting."

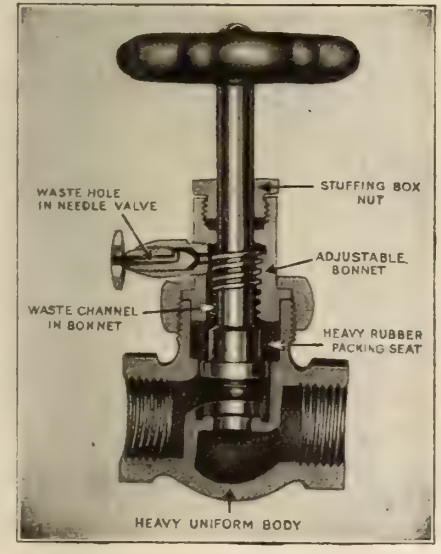
With five points of Superiority——

——five selling points in addition to the prestige that goes with the word "Emco," the trademark of its makers.

As a straight Stop-Cock or a Stop and Waste Cock it is equally adaptable.

Study the marked points in the cross sections. Pay particular attention to the arrangements for waste water :

FIRST——the adjustable bonnet which allows the needle waste valve to be placed in proper position for catching waste water.



Cross Section
"Emco" A 332 Stop and Waste Cock

SECOND——the needle valve which may be shut off independently to prevent a rush of water out the waste tube, when turning water on and off.

Every "Emco" is thoroughly tested before leaving our factory.

Write for our catalogues.

Order direct.

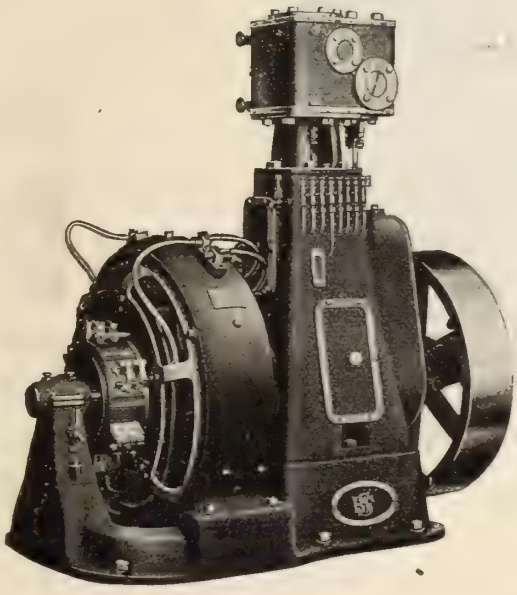
Sturtevant

TRADE MARK

Electric Generating Sets



Designed and Built to U.S. Navy Specifications!

—which fact forcibly indorses their efficiency, design, dependability, and quality of construction. Have close regulation and are suitable for all light and power purposes. Specially adapted for isolated power plants, and as auxiliaries in large plants, as well as on shipboard. They are compact, self-contained units, consisting of a Sturtevant steam engine direct connected to a conservatively rated Sturtevant electric generator. Are made with automatic lubricating systems, either gravity or forced feed. All reciprocating parts of the engine are entirely enclosed within the engine frame, which is provided with oil- and dust-proof covers. All parts are readily accessible by removing these covers. Write us for Bulletin No. 239U which details the merits, design, and construction of Sturtevant Electric Generating Sets.

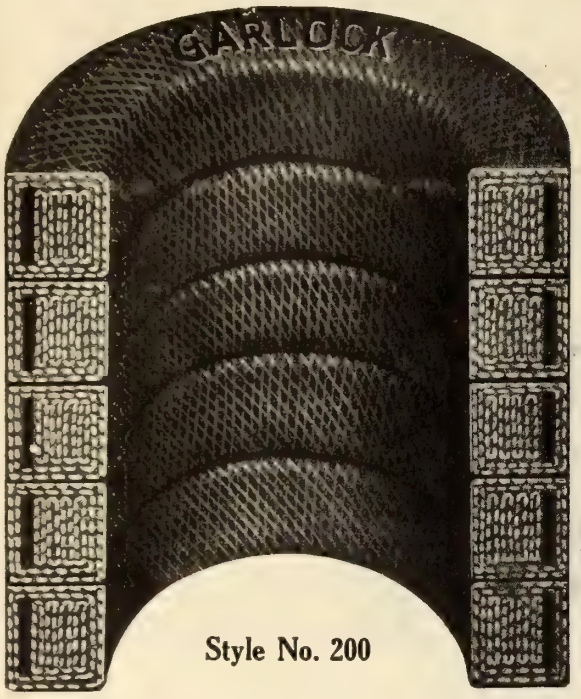
Sturtevant PUTS AIR TO WORK

Garlock High Pressure Piston Rod Packing



Style No. 200

Is built up on a core consisting of several flattened tubes.

The tubes are braided from the highest grade of asbestos yarn, and are cemented together with the best rubber friction.

The tubes are cemented only on the outside, therefore the packing is lighter per linear foot than other types of high pressure packing.

In service the tubes open under pressure and expand the packing against the piston rod.

The core of flattened tubes is backed with a cushion of high-grade rubber, so compounded as to retain its resiliency under heat.

The tube-core and rubber cushion are covered with cloth woven from the highest grade of long fibre asbestos.

Our high pressure packing is not merely smeared on the outside with graphite and grease.

Every fibre of it is saturated with a specially prepared lubricant, which does not affect the rubber cushion or friction.

The outside of the packing is coated with the best grade of floating stock graphite.

The best materials we can buy are used in the manufacture of our high pressure packing.

It is built up in rectangular form and uniform shape, and exact sizes are thereby obtained.

Asbestos packing, rolled around a rubber core and afterwards distorted by running through a square die, does not retain its shape or size.

Our high pressure packing is made by experts who have done nothing else for years but make that one type of packing.

The length of service obtained from it is greater than that secured from other makes, therefore the labor cost of applying and adjusting is less.

Our packings are sold at net weights; weights of cartons or boxes are not included.

Every pound of our high pressure packing carries with it the Garlock guarantee of satisfactory and economical service.

We will promptly replace or refund the cost of any of our packings which may prove unsatisfactory to our customers.

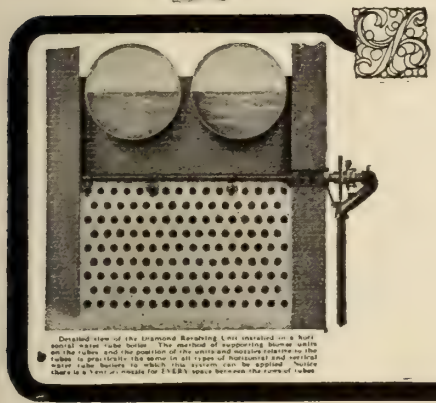
You Can Buy Them in Confidence



WHY?

BECAUSE:

CALORIZED METAL—Blower units are constructed of metal treated by the calorizing process. This process renders the metal capable of withstanding continuous temperatures of 1800 deg. F., whereas untreated iron and steel begin to oxide rapidly at 1100 deg. F. This means that Diamond units can be placed in portions of the boiler otherwise inaccessible for cleaning.

VENTURI NOZZLES—The nozzles from which the steam issues are designed on the principle of the Venturi tube. With identical pressures steam is emitted at three times the velocity possible from a straight-walled nozzle, thus insuring the absolute maximum in cleaning efficiency.

AUTOMATIC STOPS—The range of action of the steam jets is absolutely controlled. At no time can they be directed against baffles or brick work, with consequent deterioration of the latter.

GENERAL CONSTRUCTION—Stanch, rugged, mechanically correct, Diamond Soot Blowers are noted for their dependability under all conditions of service. Mechanics, material, design have all been carried as far as they can be carried, but having been carrier that far, they merge into the soot blower itself, and there the equipment stands complete, a single unit, not a list of features. Ask for Bulletin 192.

Ten-Ply Economy

You can eliminate entirely the element of guess-work in purchasing belting by specifying Dominion Friction Surface Belting, for it embodies every factor necessary in satisfactory transmission belting.

Dominion Friction Surface Belting

Conserves power by preventing slippage.
Increases production, thereby reducing cost.
Prevents idle machines and employees.
Has an extremely low upkeep cost.
Gives long and continuous service.
Careful selection of materials insures absolute dependability.
Our process makes every foot uniform.
Keeps operators contented by enabling them to produce maximum output.
Guaranteed by Canada's largest manufacturers of rubber goods.
Backed by an incomparable service of belting engineers.
Dominion Friction Surface Belting has justified every claim by more than fifty years of satisfactory performance.
Our engineers are ready to show you, without charge, how *your* transmission equipment can be put on a ten-ply economy basis.
Phone or wire our nearest branch.

GOODYEAR
MADE IN CANADA

EXTRA POWER BELTING

You can find no safer guide in selecting your belting equipment than the experience of others.

In over one thousand of Canada's plants Goodyear Extra Power Belting is being used with marked success. Scores of these have written us telling of their experience with Extra Power Belting.

Read this letter from The Dominion Steel Products Co., Limited, of Brantford, a concern noted for its progressive methods. It tells of a belting experience which must impress you.

Price was a minor factor with Dominion Steel Product, but on this alone they made a saving of $4,000.

Length of service, general efficiency, continuous operation and power saving were the determining factors in their decision to use only Extra Power Belting in their plant.

It may be that your plant is much smaller; that your saving would only be $400, but even this plus the greater efficiency of Extra Power Belting is too important for you to disregard.

You can easily prove to your own satisfaction that Extra Power would serve you as faithfully as it has the Dominion Steel Products Co.

Phone, wire or write our nearest branch, so that a man carefully trained in belting problems by Goodyear may call on you and present further evidence of the superiority of Extra Power Belting. No obligation other than fair investigation.

THE GOODYEAR TIRE & RUBBER CO. OF CANADA, LIMITED

THE DOMINION STEEL PRODUCTS COMPANY, LTD.
ENGINEERS AND MANUFACTURERS
BRANTFORD, CANADA.
October 30th, 1919.

The Goodyear Tire & Rubber Co.
of Canada, Limited,
TORONTO, ONTARIO.

Gentlemen:

Our experience with your extra power belting has been so extremely satisfactory that we feel sure you will want to hear about it.

When we opened our steel plant in 1917, the question of belting was an important one. We had to have reliable belts. So we bought some of every kind of belt offered us. We tested them. Extra Power was so superior to the others that finally we specified it exclusively. Now, every belt in the entire plant with one exception is Extra Power.

So far we have purchased over 10,000 feet of your Extra Power belting. We figure that the most best belt would have cost us close to $4000 more in the first place - and would not have given us such good service.

Most of the Extra Power belts in our plant have been in use for over two years. Little signs of wear on any of them. In fact practically all the original Extra Power belts are in use still, excepting on such severe drives as we had on our pickling machines.

You can gather from this just what we think of Goodyear Extra Power Belting.

Yours very truly,

Chas. W. Simpson
Superintendent.

LINDE

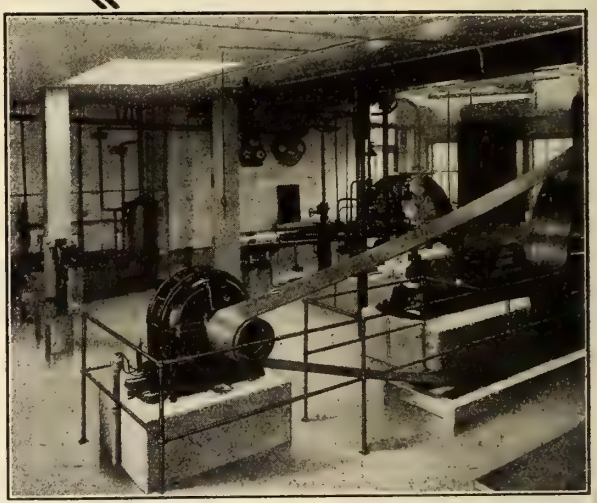
Sets the Standard for

ICE-MAKING MACHINERY

FOR EVERY PURPOSE

Economical - Efficient

100 ton Linde Refrigerating Plant in Operation.



Is your refrigerating system thoroughly efficient? If not it will pay you to install LINDE equipment. We can meet all requirements. Our new vertical enclosed type machines are suitable for plants from 1 to 30 tons. Then for heavy demands, calling for loads up to 300 tons, our horizontal frame type is guaranteed to give better service than any other refrigerating equipment on the market.

By adopting Linde equipment in the place of old and insanitary methods you increase your profits. Write to-day for information.

Every Part of Every FRICK INSTALLATION Must Be Perfect in order to maintain

FRICK SUPERIORITY

That is why Frick Refrigerating and Ice Making Equipment proves a profitable investment wherever installed.

The entire Frick line, from the smallest to the largest plant, from the smallest part to the largest part in each plant, is designed to meet our strict standard of Durability—Efficiency—Economy. Every part must be perfect in order to maintain the well-known FRICK Superiority.

Therefore, when you purchase FRICK Equipment you are assured of perfect service regardless of the unforeseen overload demand that might be placed on it sometime—assured of continued operation without danger of breakdowns in the midst of a busy season—assured of economical operation at all times—and a long life. Frick Equipment has been standing up under the above conditions for nearly a half-century, day after day, year after year, under the most severe conditions.

You can't go wrong when you specify "Frick Equipment." **Catalog on request.**

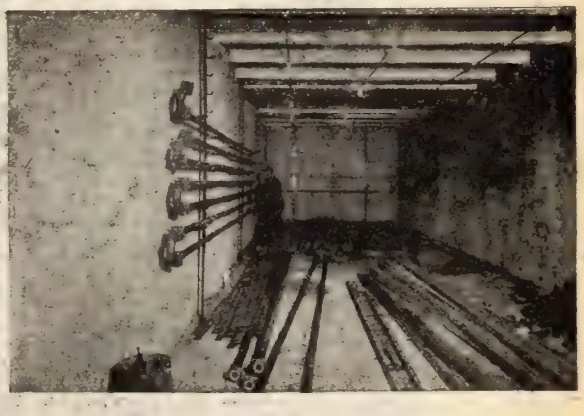
When It Pays to Re-Insulate

WHEN it becomes difficult to maintain low temperatures in your storage rooms with a reasonable amount of refrigeration, you have a good reason for believing that the material with which your plant is insulated has lost its efficiency.

Your operating cost, under such a condition, must be abnormally high. Consequently, the sooner this excessive expense is eliminated, the better for your pocketbook.

Install Nonpareil Corkboard Insulation of adequate thickness and you will have done all that can be done toward avoiding future trouble and expense due to poor insulation.

Nonpareil Corkboard is non-absorbent. That's why, as the years pass, its insulating efficiency remains practically unchanged. That's why it doesn't rot, mold or disintegrate like materials that absorb moisture. That's one reason why it pays a substantial return on the cost.



View in the plant of the Seigel-Heckinger Packing and Provision Company, Chicago, Ill. Insulated with Nonpareil Corkboard.

Send today for the 152-page book, "Nonpareil Corkboard Insulation." It contains a fund of information that every owner or manager of a refrigerating plant should keep instantly available, and there is no charge for it whatever.

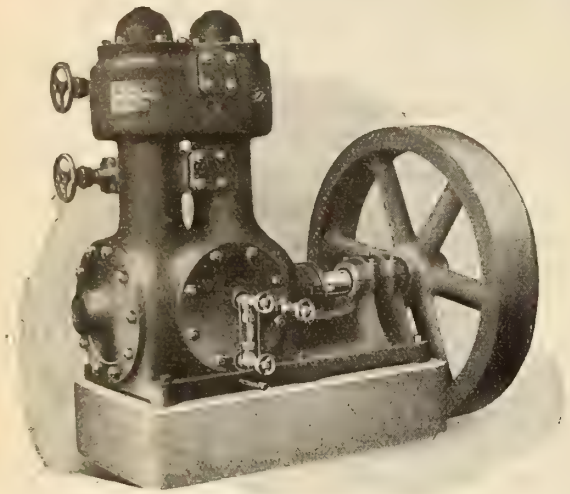
Armstrong Cork & Insulating Company, 504 McGill Building Montreal, Quebec, Canada

Also manufacturers of Nonpareil Cork Covering for cold pipes; Nonpareil High Pressure Covering for steam lines; Nonpareil insulating Brick for boiler settings, etc.; Nonpareil Cork Machinery Isolation for deadening the noise of machines; Circle A Cork Brick for cold storage room floors, and Linotile for floors in offices, residences, etc.

Nonpareil Corkboard Insulation

For All Cold Storage Rooms

Mechanical Refrigeration



BETTER Than Ice

When saving in operating cost and saving in foodstuffs are taken into consideration, the superiority of **MECHANICAL REFRIGERATION** over refrigeration by ice is beyond comparison.

But any Refrigerating Plant, to be a success and, therefore, profitable to its owner, must be properly designed and installed to meet existing conditions.

Refrigerating installations by the York Organization are based on over 30 years' experience in building Refrigerating Machinery exclusively.

From the standpoint of service, economical operation, low upkeep cost and small amount of attention required, York Enclosed Refrigerating Machines are the best available.

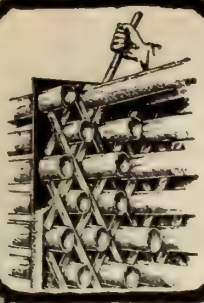
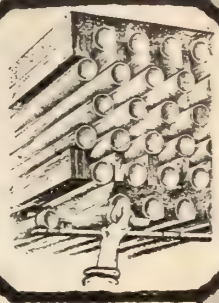
BETSON BAFFLES



VERTICAL,
Any Slope for Any Make of Boiler.

The solid one-piece baffle is the ideal baffle. It makes leakage of the valuable gases impossible. Ordinary baffles of separate brick or tile blocks have joints that cannot be made and kept tight. Betson baffles do away with these troublesome joints. The Plastic Fire Brick packs solidly in the tube spaces, and conforms exactly to the shape of the tubes.



HORIZONTAL,
Any Shape for Old and New Boilers

Permanent one-piece baffles without joints, are easily made with Betson's Plastic Fire Brick. They do not crack under expansion, and are always gas-tight. Any one around the plant can do the job. No forms required. No special tools necessary. Betson baffles can be made in any size, shape or slope, for horizontal and vertical type boilers of any make.

Comes ready for use, in the yellow-top barrel.

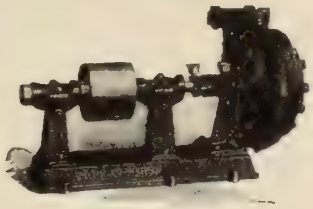
AMERICAN-MARSH PUMPS

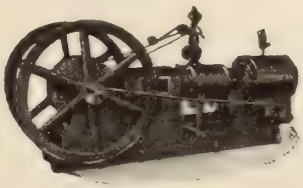
SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors

Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

The Water Powers of British Columbia, II

A Further Abstract From the Report by the Commission of Conservation, Giving Information in Regard to Actual Installations Which Are Developing Power for Municipal and Private Use

IN British Columbia there has been considerable development of water-powers, both for municipal and industrial purposes. In fact, development of this resource has contributed much to the general advancement of the Province. The more important of the existing installations are described briefly below. Such descriptions not only show what course has been pursued upon various types of streams, but also set forth the general design and character of such equipments as have been employed in the respective developments.

British Columbia Electric Railway Co., Ltd.

The history of hydro-electric development in British Columbia is intimately associated with the early activities of what is now the British Columbia Electric Railway Co., Ltd. In 1887, the Vancouver Electric Illuminating Co., Ltd., installed an electrical plant. In 1889, a second company, known as the Vancouver Electric Railway Co., Ltd., was formed. The following year, the two companies were merged and their railway lines electrically operated. In 1890, a New Westminster interurban system and a Victoria (Vancouver Island) system were commenced. These were merged into one company, known as the Consolidated Railway Co., Ltd., and their lines were operated under this control until 1897, when the British Columbia Electric Railway Co., Ltd., was formed, and, subsequently acquired the assets of all the companies above referred to.

Confidence in the development of the territory to be served, the directors of the company, at the outset, formulated their plans with respect to future development. There is, no doubt, that the remarkable development which has taken place in the districts around Vancouver, New Westminster and Victoria has been largely assisted by the liberal expenditures of the British Columbia Electric Railway Co. at a time when settlement in the province was being stimulated. The company's operations now extend over a field which contains over half the population of British Columbia.

The supply of power for the company's various undertakings is obtained from five power stations. On the mainland, the Vancouver Power Co., a subsidiary, operates a large and up-to-date hydro-electric plant on the north arm of Burrard Inlet. It also operates a steam plant in the city. For Victoria and vicinity, the company owns and operates a hydro-electric plant at Goldstream, and an auxiliary steam plant at Brentwood Bay. The Vancouver Island Power Co., a subsidiary, operates a hydro-electric plant at Jordan River.

The plant at Burrard inlet, known as the Coquitlam-Buntzen development, is the largest in the province. It consists of two power-houses at sea-level, utilizing water diverted from Coquitlam Lake, through a tunnel 2¼ miles long, to Lake Buntzen, a small lake 400 feet above sea-level, and but a short distance from Burrard inlet.

The utilization of Lakes Coquitlam and Buntzen for power purposes was decided upon sometime prior to 1898, and power was first supplied from power-house No. 1 to Vancouver in December, 1903. The original scheme comprised raising Coquitlam Lake, by means of a rock-filled crib dam, about 11 feet above its average summer level. Water so stored was delivered through a tunnel 2¼ miles long — then stated to be the longest purely hydro-electric tunnel in the world — to Buntzen Lake, at the outlet of which a concrete intake dam, 54 feet high, was built across the canon.

WESTERN CANADA POWER CO. STAVE FALLS DEVELOPMENT.

The rapid development and growth of the district around Van-

couver demonstrated that the demand would, in a short time, exceed the maximum capacity of the plant. After careful investigation, was decided to enlarge the tunnel connecting Lakes Coquitlam and Buntzen, and build a new dam to increase the storage capacity of Coquitlam Lake. Extensive additions were also provided at the power house.

SIMILKAMEEN RIVER POWER PLANT OF THE DALY REDUCTION CO. SHOWING FOREBAY, STEEL PENSTOCK AND POWER HOUSE. HEAD DEVELOPED 67 FT., HEDLEY, B.C.

By the time the enlargement of the tunnel was completed, in June, 1911, the demand on the company's system necessitated the construction of a second power-house. Work on the extension of the new dam and of No. 2 power-house completes the hydro-electric development of the Coquitlam-Buntzen schome.

Coquitlam Lake

Coquitlam Lake is about 7 miles in length, with an average width of about one-third of a mile. Its original area was about 2,190 acres. The area of the watershed is approximately 105 square miles. The surrounding mountains rise precipitously to a height of 3,000 to 6,000 feet and the greater portion of the watershed is well timbered. The annual precipitation during the last eleven years has averaged over 150 inches. The snowfall is very heavy and remains on the higher peaks until late in the summer. To provide storage to enable the entire runoff from the watershed to be utilized, it was necessary to raise the level of the lake; the spillway of the new dam is at elevation 503 feet, 60 feet above the old dam.

The New Dam

The new dam is of the hydraulic-fill type, with heavy rock toes. It is built at the outlet of the lake, upon a natural barrier. Its crest elevation is 518 feet, and the maximum height of the dam, above the lowest point of the foundation on the centre line, is 100 feet. The length along the crest, including the spillway, is 1,200 feet. The slope of the upstream face is 1 in 5, and of the downstream face 1 in 2 to 1 in 4. The spillway is cut through a solid rock spur at the east end of the dam. The concrete sill at the entrance to the spillway is at elevation 503, being 15 feet below the crest of the dam. During the construction of the dam, the outflow from the lake was carried around the dam site in a tunnel driven under the spillway, and designed to carry 12,000 c.f.s. For controlling the flow through this tunnel, permanent gates are placed in a concrete tower at its upper end.

As the city of New Westminster has drawn its water supply from Coquitlam Lake since 1892, and as the raising of the lake level rendered the original municipal intake works useless, an entirely new intake has to be provided. For the protection of the New Westminster water supply, extensive clearing operations along the shores of the lake were carried out by the company.

Hydraulic Tunnel

The total length of the tunnel which conveys water from Coquitlam Lake to Lake Buntzen is 12,650 feet. It originally had a square section, about 9 by 9 feet, with rounded corners, and was designed to carry 500 c.f.s. The area of the section was subsequently enlarged to 192 sq. feet, which is sufficient for the ultimate carrying capacity required by the scheme. The intake to the tunnel was rebuilt when the new dam was constructed. It consists of a heavy masonry retaining wall, founded on bedrock, and built against the steep hill above the tunnel entrance. This entrance is protected by a rack, and two independent sets of head-gates are provided for controlling the flow of water through the tunnel. One of these gates is of the Coffin type, 9 feet in diameter; the second set consists of two Stoney sluice gates placed side by side.

A range of mountains, which reaches an elevation of 4,000 ft., separates Coquitlam and Buntzen lakes. The watershed of Lake Buntzen is 7 square miles and the average annual precipitation during the last twelve years has been over 110 inches. The area of the lake is about 500 acres, and, by the construction of a concrete dam, 54 feet high and 361 feet long on the crest in a canon below the outlet, the lake has been made into an excellent forebay. The crest of the dam is 400 feet above sea-level. Ten outlets 24 inches in diameter and two outlets 24 inches in diameter were provided. To these are connected the pipe-lines which convey water to power house No. 1.

Power House No. 2

The water for power house No. 2 is obtained from Lake Buntzen, through a concrete-lined pressure tunnel, 14 feet 8 inches in diameter and about 1,800 feet long, driven through solid rock and controlled by three Doble needle intake valves, placed with their seats on a concrete foundation on the bottom of the lake. These needle valves are operated by oil pressure, and an outer cylinder is provided which may be lowered down to a horizontal seat, enabling them to be inspected without the use of a diver. Near the lower end of the pressure tunnel and close to the top of the hill a steel surge tank, 50 feet in diameter, is provided, and from this point three steel pipe lines conduct the water to power house No. 2. These pipe lines are each 8 feet 6 inches in diameter at the surge tank and taper to a diameter of 7 feet at the power house. About 200 feet from the power house the pipe lines pass through tunnels driven in the solid rock. A Pelton-Doble-Venturi butterfly valve is installed in each pipe-line.

No. 1 Power House

No. 1 power house is situated on the east shore of the north arm, about sixteen miles from Vancouver. The buildings were erected from the granite blasted out to form the site for the generating station. The main floor is about 5 feet above high water. The original in-

stallation has been added to from time to time. Steel penstocks convey water from the intake dam at the outlet of Lake Buntzen. Units Nos. 1 to 4 are each supplied by means of a pipe line 48 inches in diameter and 2,000 feet in length. Two pipe lines 60 inches in diameter are provided for the fifth unit. One pipe line, 84 inches in diameter at the upper end and tapering to 72 inches at the power house, is provided for the sixth unit, and a similar pipe line conveys water to unit No. 7. The present equipment consists of four 3,000 h.p. Pelton water-wheels, driving four 1,500 k.w., 3-phase, 60 cycle Weston House generators; one 10,500 h.p. Pelton water-wheel, driving one 5,000 k.w., 3-phase, 60-cycle Canadian General Electric generator; one 10,500 h.p. Doble water-wheel, driving one 5,000 k.w., 3-phase, 60-cycle Dick-Kerr generator, and one 10,500 h.p. Doble water-wheel, driving one 5,000 k.w., 3-phase, 60-cycle Canadian General Electric generator. All of the above units have a speed of 200 r.p.m. and are of the horizontal type, the water-wheel and generator being, in each case, mounted on the same shaft. In addition to the above equipment there are four exciter units, each a direct current generator with an induction motor at one end of the shaft and the water wheel on the other. The transformers and high tension switching equipment are housed in a separate building erected on the hillside behind the power house.

In 1911, as it was impracticable to build further extensions to power house No. 1 a new site was selected, about one-third of a mile south. Power house No. 2, of reinforced concrete, erected on solid rock, is a fine building of massive proportions and careful design. It contains three horizontal units, each consisting of four Pelton-Doble water-wheels, the combined capacity of which is 13,500 h.p. They are mounted on one shaft, together with the revolving field of a Dick-Kerr 8,900 k.v.a., 3-phase, 60-cycle alternator. Close to the back wall of the power house the main pipe line divides into four branches, each branch supplying water to one wheel of the unit. The speed of each unit is 200 r.p.m., and regulation is secured by a Lombard governor, auxiliary relief nozzles being provided. There are three 300 k.w. exciter units, consisting of a Dick-Kerr induction motor generator set, direct driven by one Pelton-Doble water wheel mounted on one end of the shaft. The transformer room and switching equipment are located in the same building.

Current is generated at 2,200 volts and stepped up to 34,600 volts for transmission to substations in Vancouver and adjacent territory. It is understood that the transmission voltage will soon be increased to 60,000 volts. The two outgoing circuits from plant No. 1 are carried on wood poles; the other two circuits —the outgoing lines from plant No. 2— are carried on steel towers. A tie-line connects power houses Nos. 1 and 2

The plants and equipment above described reflect great credit upon the company and its engineers.

Victoria Power Supply

Power and light are supplied to the city of Victoria by the British Columbia Electric Railway Co. and its subsidiary, the Vancouver Island Power Co.

There are two hydro-electric plants, one at Goldstream, twelve miles from Victoria, and the other at Jordan River, forty miles distant. There is also a steam electric plant at Brentwood Bay, twelve miles distant.

Prior to 1898 the city was supplied with light and power from steam plants situated within the city limits, and also owned by the British Columbia Electric Railway Co.

Goldstream

In September, 1917, an agreement was made with the Esquimalt Waterworks Co. for the supply of a maximum and minimum daily amount of water to the British Columbia Electric Railway, for a hydro-electric plant to be built at Goldstream. This agreement stipulated that all water supplied for power purposes would be returned to the waterworks company's reservoir below the power house site, and in condition suitable for domestic use. 1898 the British Columbia Electric Railway Co. constructed its Goldstream power house.

The Esquimalt Waterworks Co. has five storage reservoirs at Goldstream, situated at elevations of from 1,200 to 1,500 feet above sea level. From them the water flows first to a balancing reservoir of 3,500,000 cu. ft. storage capacity, and at an elevation 1,100, then through the Goldstream plant and thence to a lower reservoir at elevation 450, affording a head of 650 feet. The capacity of these reservoirs is sufficient to take care of considerable daily fluctuations. The penstock bringing water from the balancing reservoir to the power house consists of 4,000 feet of 33 inch, and 4,000 feet of 30 inch steel pipe.

The initial equipment, which went into operation in September, 1898, consisted of two Pelton water wheels of 600 h.p. each, direct-connected to two 350 k.w., 3-phase, 60-cycle, 700-volt generators. In 1903 a third unit of 500 k.w. was installed. In 1905 a fourth direct-connected unit of 1,000 k.w. capacity was added, and is driven by two water wheels, each of 1,000 h.p. The energy is stepped up from 700 to 17,500 volts and transmitted over a two-circuit, single-pole transmission line twelve miles long, to Rock Bay sub-station at Victoria.

Jordan River

The second hydro-electric plant supplying power to Victoria, is situated at the mouth of Jordan River, which flows into the strait of Juan de Fuca, about 40 miles west of the city. The Jordan is a mountain stream, flowing in a southeasterly direction through a deep and precipitous valley. It drains about 61 square miles—the greater portion lying at an elevation of over 1,200 feet. The entire watershed is heavily forested. The drainage area above the intake,

REVELSTOKE HYDRO-ELECTRIC DEVELOPMENT, ILLECILLEWAET RIVER. SHOWING INTAKE DAM AND WOOD STAVE PIPE LINES.

including the area above Alligator Creek diversion, is 50 square miles.

The precipitation on the western slope of Vancouver Island is heavy. At the mouth of the Jordan river it averaged, during the period 1908 to 1915, about 70 inches annually, and, in the vicinity of Bear Creek, at an elevation of 3,600 feet, an average of about 95 inches has been recorded during the last five years. Probably the average over the whole watershed exceeds 90 inches per year. At the higher altitudes, there is a heavy fall of snow during the winter months, which often remains on the ground until June or July. When this snow disappears, the flow of the Jordan falls off very rapidly. To compensate for low-water flow, storage reservoirs have been provided. Although there are no large lakes in the watershed, five sites, suitable for storage dams, have been located. Two of these dams, known as the Bear Creek dam and the Jordan dam, are now completed.

TYPE OF CONCRETE LINED DITCH.

Bear Creek flows into the Jordan 3½ miles above the main diversion dam. The storage dam on this creek lies about a mile above its junction with Jordan river. It is an earth hydraulic-fill embankment. Its greatest height is 57 feet, and the length, on the crest, is 1,020 feet. Impermeability is secured by a sheet-steel-piling curtain wall driven to a bedrock across the valley. It is proposed, ultimately, to raise this embankment to 75 feet. A spillway is excavated out of solid rocks at the north end of the dam. This dam forms a lake of 285 acres, and provides storage of 328,000,000 cubic feet. The area of Bear Creek watershed above the dam is about 8 square miles. The dam was commenced in November, 1910, and completed in April, 1912.

The Jordan dam (see Plate 4) is on the Jordan river, immediately below the junction of Wye Creek. Here the canon narrows, and is crossed by a ridge of rock which extends well up both sides of the canon. This site was early recognized as the best for a permanent dam.

The Jordan dam is a hollow, reinforced-concrete structure of the Ambursen type. Its extreme height is 126 feet above sea-level. The upstream face of the dam consists of a reinforced-concrete face, or deck, inclined at an angle of 45 degrees. This is supported on concrete buttresses, spaced 18 feet centre to centre. These buttresses are 12 inches thick at the top, and increase, by steps of 12 feet in height, to a thickness of 42 inches at the bottom of the highest buttress. The down-stream edge has a batter of 1 to 4 from the base to a point 18 feet below the crest, above which point it is vertical. A spillway, 305 feet long, with a crest 8 feet below the top of the dam, is provided near the east end. The spillway has a curved crest and rollway apron, and provides for a discharge of 23,000 cubic feet per second.

The main flume, for about 5½ miles, follows the eastern side of the Jordan valley from the dam to the forebay reservoir. The side of the valley is steep for the entire distance, and precipitous in places. The flume is 6 by 6 feet, with a grade of 1 foot in 1,000, and designed to carry 175 c.f.s. Five sand boxes, with gates in the side of the flume, are provided.

The forebay consists of a small artificial lake of 4,350,000 cubic feet storage capacity, formed in the flat between two hills by two earth-filled embankments. These were built of the material excavated from the higher ground lying between them, thus adding to the capacity of the reservoir. The maximum height of each dam is 35 feet. Suitable spillway is provided. Two steel pipes, with 54-inch diameter sluice gates, connect at the dam to the pipe-lines which convey water to the power-house. One provides water for units Nos. 1 and 2, the second serves unit No. 3. The pipe-line serving units Nos. 1 and 2 is 44 inches in diameter and 3,010 feet long. At its lower end a Y is provided for two pipes, each 6,280 feet long and 36 inches in diameter at the upper end, tapering to 30 inches diameter at the power-house. Both pipe-lines are controlled by gate valves placed just below the Y pipes. The pipe-line for No. 3 unit has a total length of 9,290 feet, and tapers from 54 inches in diameter to 48 inches at the power-house. The head at the power-house is 1,145 feet.

The original power-house, as completed in 1911, was a concrete structure with two units each of 4,000 kw. capacity. Recently, it has been enlarged; a new 8,000 kw. unit has been added, space has been provided for a fourth unit, and a new high-tension switch-room has been built. The power-house is of reinforced concrete, resting on concrete piles, 12 inches in diameter, penetrating to bed-rock at a depth of 45 to 75 feet. It contains three units. Units Nos. 1 and 2 each consist of a single Doble water-wheel of 6,000 h.p., coupled direct to a 4,000-k.v.a., Allis-Chalmers-Bullock, 3-phase, 60-cycle generator, at a speed of 400 r.p.m. Speed regulation is obtained by a Lombard oil pressure governor. No. 3 unit consists of one 8,000-k.v.a., 3-phase, 60-cycle, Canadian General Electric generator, driven by two Pelton-Doble water-wheels, one mounted on each end of the shaft. The water-wheels are together rated at 13,000 h.p. Each wheel of No. 3 unit is provided with a separate oil-pressure, relay-type Pelton-Doble governor. There are three exciter units, two of which consist each of a 100-kw., 125-volt, d.c. generator, direct-driven by a 150-h.p. water-wheel, and also by a 150-h.p. induction motor. The third is a 200-kw., 125-volt, d.c. generator, on the shaft of which are mounted a 300-h.p. induction motor and a 200-h.p. water-wheel. Water is supplied to the exciter units from a header connected to all three pipe-lines. Valves are arranged so as to permit any exciter unit to be driven by water from any pipe-line.

Current is generated at 2,200 volts, and stepped up to 6,000 volts for transmission to Victoria. The transmission line is about 37 miles long. For about 15 miles the line, which is of aluminum cable, follows the shore, and then strikes inland to Victoria, terminating in the Rock Bay sub-station. The poles are of cedar, cut along the line. Cross-arms for two circuits are provided, but only one has been installed.

City of Kamloops

Kamloops, in 1915, completed the first portion of its hydro-electric development on the Barriere River, which falls into the North Thompson from the east, about 40 miles from the city. The total drainage area of the Barriere is about 350 square miles. It divides 12 miles above its mouth, and both branches have their source in the mountainous district between Adams Lake and the North Thompson River. The watersheds are generally well wooded with fir, spruce and cedar, but, in some parts, there is a dense covering of small growth. The snowfall of the district is heavy, and severe weather is occasionally experienced. On both branches of the river, there are lakes which afford good storage sites; one of these, Barriere Lake, through which the main stream, the north branch, flows, has been utilized for storage for the present development. The area of the watershed above the outlet of the lake is about 135 square miles, and Barriere Lake has an area of some 3,600 acres. A storage and intake dam has been built at the outlet of the lake, and, from this point, water is conveyed to the forebay in a 5 by 8-foot flume, 18,000 feet in length. The forebay is fitted with sluice-gates and provided with spillway. Penstocks, 500 feet long, convey the water to the power-house, which is situated on the north bank of Barriere River. The head developed is 190 feet.

The present power-house has been built to accommodate four units, two of which are at present installed. Each unit consists of a 1,200-h.p. Francis turbine, manufactured by the Platt Iron Works, direct connected to a 750-k.v.a., 3-phase, 60-cycle alternator, supplied by Canadian Westinghouse Co., generating current at 2,300 volts. These sets run at 720 r.p.m., and are controlled by direct-acting Lombard governors.

The voltage is stepped up to 44,000 volts, for transmission to Kamloops. It is anticipated that there will be a considerable demand for power to pump water for irrigation along the North Thompson valley, which is traversed by the transmission line. The ultimate development possible on the Barriere River is between 16,000 and 20,000 h.p.

To provide against interruption to the hydro-electric service, due to winter troubles or breakdowns on the long transmission line, it was deemed expedient to provide a steam auxiliary plant in the city. As the demand for increased power was urgent, and a steam plant was more easily constructed, it was first completed. The power-house building is situated in Kamloops, near the banks of the Thompson River. It is of reinforced concrete, and contains the pumping plant for the domestic supply to the city. The boiler room contains four Babcock & Wilcox boilers, of 250 h.p. each, designed to operate at 160 lbs. pressure. The turbine-room equipment consists of two Curtis turbo-alternators, of 900 kw. capacity, built by the General Electric Co. The alternators are 3-phase, 60-cycle, 2,200-volt machines, operating at 3,600 r.p.m. Motor and steam-driven exciters are provided, also the usual condensing and auxiliary plant. The high-tension sub-station receives current from the 44,000-volt lines from the Barriere River plant, and reduces the pressure to 2,300 volts for local distribution. Complete switching equipment is provided.

The city now has at its disposal about 5,000 h.p. of electrical energy. As the demand for power increases, it is intended to increase the capacity of the plant at Barriere River and retain the steam plant as a standby.

The cost of the initial hydro-electric development is about $140 per h.p.; the installation of a further 4,000 h.p. will reduce the average cost per h.p. to $90, and it is estimated that, when the ultimate development is carried out, the cost per h.p. will be reduced to about $80.

City of Nelson Development on Kootenay River

The city of Nelson has constructed a hydro-electric power plant at Upper Bonnington Falls, on the south side of the Kootenay River. This plant supplies light and power to the city, and for mining purposes in the adjacent territory.

The site selected for this development was examined and staked at the end of 1900, the water record was granted on January 15, 1901, and the city secured title to the site for the proposed plant January 22, 1903. The plan adopted provided for a plant of four units, each capable of developing 1,250 h.p. under the minimum head of 40 feet available at high water, or 1,675 h.p. under the 60 feet head available at low water. Work was commenced April 3, 1905, but, owing to trouble, chiefly in connection with the disposal of the excavated material, the work was held up from time to time. Further delays occurred in the shipment of the plant, and it was not until December 28, 1906, that water was turned on the turbine of the first unit installed.

The power-house is of brick on a concrete foundation. The foundation is raised to the elevation of the turbine floor for four units, but the superstructure is completed for two units only. The present installation consists of two Allis - Chalmers turbines, with a maximum capacity (at highest head) of about 2,000 h.p. each. These are directly connected to Allis-Chalmers 3-phase generators, one of 750 kva., and one of 1,000 kva. The umbrella type of construction adopted enables full advantage to be taken of the total head available at any stage of water. Speed regulation is

WOODEN FLUME SKIRTING MOUNTAINSIDE

secured by oil-pressure governors. Power at 12,000 volts is transmitted 9½ miles on a right-of-way purchased by the city. The transmission line consists of two circuits of stranded aluminum cable carried on cedar poles. The city of Nelson operates its own electric street car service.

City of Prince Rupert Development at Woodworth Lake

Woodworth Lake, situated about 7 miles from Prince Rupert, has an area of 500 acres. The watershed area is about 9.5 square miles, consisting mostly of steep hillside, with very little timber on the upper slopes. The mountains rise to about 4,000 feet. There are several snowfields, but no glaciers within the drainage area. This project was investigated in 1910-12, and plans placed in operation in November, 1914.

Investigation of stream-flow revealed a high run-off, and it is anticipated a flow of from 80 to 100 sec. feet will be available for power and domestic supply. A storage dam 35 feet in height was built. The power-house is 7,500 feet below the lake, and a head of 330 feet is developed by means of a 45-inch steel pipe 7,800 feet long. The power penstock is also partly used for water supply purposes. Immediately behind the power-house is attached an 18-inch steel pipe-line, 14,000 feet long, which connects with an existing 18-inch water supply pipe near the auxiliary pumping station at Shawatlans Lake, about 5 miles from the city.

A power-house of simple design has been erected. The initial installation consists of one water-wheel of 1,650 h.p. capacity, direct connected to a 1,125 kva., 3-phase, 60-cycle, 4,400-volt, at 514 r.p.m., Canadian General Electric generator. Close regulation is secured by oil-pressure governor. A 15-kw. exciter is connected to the main units. Voltage is regulated by a Tirrell regulator. The energy is transmitted to the city over a single circuit wood-pole transmission line.

City of Revelstoke Development on the Illecillewaet River

The Illecillewaet River drains about 480 square miles of the western slope of the Selkirk Range, and discharges into the Columbia River near Revelstoke. Its valleys and the lower slopes of the mountains are heavily wooded; above the timber line, there are numerous snowfields and glaciers. The precipitation in the valley varies from 42 inches near Revelstoke to 58 inches near Glacier, and, over portions of the watershed, no doubt exceeds the latter figure. The winters, with occasional spells of very low temperature and heavy snowfall, are severe, and serious ice troubles have been encountered. The river is a typical mountain stream. (See Plate 16.) Its flow varies from about 250 sec.-feet to over 9,000 sec.-feet.

LOWER BONNINGTON FALLS, KOOTENAY RIVER, WEST KOOTENAY LIGHT AND POWER CO.'S PLANT NO. 1 IN FOREGROUND. UPPER BONNINGTON FALLS IN BACKGROUND.

The Revelstoke hydro-electric development is situated about 1½ miles from the mouth of the river. A concrete dam, 56 feet high, has been built across the canon, creating a pondage of about 10 acres. Two 6-foot diameter wood-stave pipes carry the water about 1,200 feet downstream to a power-house, where a head of 72 feet is developed.

The power-house equipment consists of a 900-h.p. Francis turbine, driving a 450-kva. Canadian Westinghouse generator, at a speed of 450 r.p.m.; also a 1,400-h.p. Escher-Wyss-Francis type turbine, direct connected to a 750-kva. Canadian Westinghouse generator running at 360 r.p.m. Exciter units, in each case, are direct connected. Speed regulation of the 1,400-h.p. unit is secured by an oil-pressure governor and of the 900-h.p. unit by a mechanical governor current, at 2,300 volts, 3-phase, 60-cycle, is supplied to Revelstoke and to the shops of the Canadian Pacific Railway. To ensure against interruption to service, due to low water, ice, or other causes, a gas engine auxiliary plant has been provided.

Western Power Company of Canada, Ltd., Development on the Stave River

The first application for a water record at Stave Falls was made in 1899, by the Stave Lake Power Co., Ltd. In 1909, the Western Canada Power Co., Ltd., was formed, for the purpose of supplying power, in ample quantity and at prices sufficiently attractive, to encourage the establishment of industries in Vancouver and its vicinity. In June, 1909, the company took over the Stave Lake development, and the first unit was placed in commission in January, 1912.

Stave Lake lies to the north of the Fraser River, and about 35 miles from Vancouver city. The watershed has only been partially explored. It has an area estimated at about 450 square miles, and lies among the granite peaks of the Coast mountains, which, rising high above the timber-line to over 8,000 feet, carry perpetual snow and numerous small glaciers. The length of the river, from its source in a glacier to its confluence with the Fraser at Ruskin is about 60 miles.

The original elevation at Stave Lake was about 230 feet above sea-level, with a fluctuation between high and low water of about 15 feet. The lake was 9 miles long by about a mile wide with precipitous shores to the east and west. From the foot of the lake to Stave Falls the river descended 80 feet. Below the falls, for a distance of 4 miles, there is a series of rapids, and the river finally debouches through a narrow granite gorge into the Fraser River.

The present Stave Lake development utilizes the head available in the immediate vicinity of the falls and also the head concentrated at that point by a dam, which drowns the rapids above and the large areas of low land at the head and the lower end of the lake. The working head varies between 100 feet at low-lake level and 120 feet with full reservoir. Very careful preliminary investigation was made of hydraulic conditions. This included extensive surveys, measurements of water supply, precipitation, flood conditions, etc.

The raising of the level of Stave Lake

materially increased its area. At a stage of 269, the lake extends for 18 miles above the dam, and its area at this stage is about 24 square miles. This reservoir will have a storage capacity of nearly 370,000 acre-feet, sufficient to maintain a mean flow of about 3,150 sec.-feet in lowest years yet recorded and somewhat more in average years. The average flow over a number of years has been about 4,000 sec.-feet, but the physical conditions at Stave Falls are such that it is not economically feasible to build a dam to an elevation of about 300 feet, which stage would be required to completely store the mean flow over the years of record. The most economical height of dam is that which would maintain a flow line at elevation of about 264 feet above sea-level.

In its natural state the main river divided into two branches about 400 feet above the falls, re-uniting about one-half mile downstream. The intake and sluice dams have been built at the head of the falls. The power house is built across the western channel, below the intake dam, and the eastern channel is utilized for the overflow and flood discharge from the sluice dam. When the lake is raised to the ultimate elevation proposed, the present sluice dam—now designed to take practically the whole flood discharge of the river—will be built up solid, with a row of gates on top for partially controlling the flood discharge and the main flood discharge will pass down an old channel about one-quarter mile to the east of the falls, known as the Blind Slough. For a flow-line at elevation of 239 (sea-level), the Blind Slough forms a natural rock spillway-dam 400 feet long, with a channel 50 feet wide and 20 feet at one side. The deep portion is at present closed by a timber crib-dam, and a temporary spillway of low elevation is built across the remainder of the channel. The permanent structure will consist of concrete piers, with log sluices, and will make ample provision for flood discharge.

The sluice dam is 150 feet wide, built of reinforced concrete. The piers are 8 feet wide, with five stop-log openings, each 22 feet wide. The intake dam is of concrete on a granite foundation. It is 160 feet long, and, when completed, will be 70 feet high. There are four main intakes, with necessary screens. The intake gates are of the radial type and weigh 23 tons each. In addition, there are two gate chambers for pipes to the exciter units.

The main penstocks are 14 ft. 6 in. diameter. The upper ends are imbedded in the concrete and belled out to 19 feet, giving a maximum velocity at the mouth of 4.6 feet per second. There are two separate 46-inch steel penstocks for the exciter units and oil pumps. The penstocks are not more than 150 feet long, thus securing excellent regulating conditions. The tailrace, 1,500 feet long, was excavated to a depth of about 30 feet.

The power house, constructed of reinforced concrete on solid rock foundation, was designed for four main units, but first completed for two, with the necessary auxiliary equipment. Each main unit consists of a 13,000 h.p., double horizontal turbine of the Francis type, built by the Escher-Wyss Co., of Zurich, Switzerland, direct coupled to a 9,000 kw., 3-phase, 60-cycle, 4,400 volt Canadian General Electric generator. There are two exciters, each 250 kw., 125 volts, driven by its own turbine, and each capable of exciting four machines. Regulation is secured by governors of the oil-pressure type, the oil pumps being driven by individual impulse wheels.

The current is stepped up to 13,000 volts and 60,000 volts, and, at the higher tension is transmitted 32 miles to Ardley, a point about midway between Vancouver and New Westminster. Another line runs south to the international boundary, where it connects with a line built by the Puget Sound Traction, Light and Power Co. into Bellingham, the total distance being 47 miles. At 13,000 volts the current is transmitted to points within 20 miles of the generating station.

From the tailrace of the existing plant to the mouth of the river, an additional fall of 130 feet is available. Two plans of developing this fall have been considered. One plan contemplates a concentration of the head at the narrow gorge near the mouth by the construction of a dam 165 feet high. The second plan provides for two dams, each 65 feet high, one at the above gorge, and one about a mile below the present plant. The latter plan involves less initial expenditure, and would enable the plant capacity to be increased by stages with the increasing demand until ultimately turbines aggregating some 120,000 h.p. had been installed. This would complete the development of the Stave River.

West Kootenay Power and Light Co.,

The West Kootenay Power and Light Co., Ltd.—a pioneer in the development of water-power on a large scale in British Columbia—owns and operates three hydro-electric generating plants. Two of these are at Bonnington Falls, on the Kootenay River (see plate 15), and the third is situated on the Kettle River, about twelve miles below Grand Forks.

These developments are the largest and most important in the interior of British Columbia, and furnish power and light to the cities of Trail, Rossland, Grand Forks, Phoenix, Greenwood, Boundary Falls, and to other users within the radius of the transmission lines.

In 1897, the gold and copper mining industries in the Kootenay country were practically undeveloped. At that time a small smelter was in operation at Trail, and mining operations were in progress at Rossland, but the total amount of energy utilized at these two points probably did not exceed 1,000 h.p. In this section of British Columbia, the mines and smelters are the largest consumers of power, and, to-day, the connected load in the vicinity of Rossland alone has increased to over 6,000 h.p. The great development of the mining and allied industries has been largely facilitated by the supply of power made available by the developments of the Kootenay Power and Light Co.

Plant No. 1, Lower Bonnington Falls

The first plant, now known as Bonnington Falls, Plant No. 1, was commenced in 1897. It is situated at Lower Bonnington Falls, and has a capacity of 4,000 h.p. under a normal working head of 34 feet. The equipment consists of three units; one turbine unit of 2,000 h.p., direct connected to one generator of 1,500 kw.; and two turbine units of 1,000 h.p., each direct connected to generators of 750 kw. The turbines are twin runners of the horizontal type. The generators are 3-phase, 60-cycle. The sets run at a speed of 180 r.p.m. Current is generated at 1,100 volts and stepped up to 22,000 volts.

Plant No. 2, Upper Bonnington Falls

Plant No. 2 is situated at Upper Bonnington Falls, a short distance above No. 1. The power house is of reinforced concrete, situated in the channel immediately below the falls, on the north side of the river. The building and intake structure form a wing dam, which diverts the water to the turbines. The head developed is 63 feet at low-water stage, but, during high water, it is reduced to 56 feet by backwater caused by the contracted area of the channel a short distance below the falls. The working head, it is estimated, may be increased to 70 feet by the removal of obstructions in the channel below, and the erection of a low dam across the river above the falls. This work is now underway.

Space in the power house provides for four main generating units, two exciter units, and the necessary transformers and switching apparatus. The main units, all of which are now installed, consist of two 8,000 h.p. Francis turbines, with vertical shaft, each direct connected to a 5,625-kva., 3-phase, 60-cycle Canadian General Electric generator of the umbrella type, and two 9,000 h.p. Francis turbines with vertical shaft, each direct connected to similar generators of 7,500 kva. The sets run at a speed of 180 r.p.m., and regulation is by oil-pressure governors.

Current is generated at 2,200 volts, and stepped up to 60,000 volts, at which it is transmitted to sub-stations at Greenwood, Rossland, Grand Forks, Phoenix and Boundary Falls—the last named being 84 miles from Bonnington.

The Increasing of Power Plant Efficiency

The Human Factor is of Vital Importance in the Problem of Increasing Power Plant Efficiency. This Element is Discussed in This Article Which Deals With Various Phases of the Subject

By ROBERT JUNE, Mechanical Engineer

IN previous articles, we have discussed various power plant instruments, and a number of types of equipment, indicating conditions under which these could or could not be used advantageously, and suggesting methods of effecting economies in operation. Since our discussions have followed the lines of accepted good practice, the points brought out and methods suggested, have the sanction of authority and constitute a valuable plan of procedure in our program of increasing power plant efficiency.

It is one think to lay out a program, however, and another to execute it, as anyone who has ever tried to stimulate the morale of an operating force and increase the efficiency of power production, knows. The problem of economical boiler and furnace operation contains a large psychological factor which must be taken into account, if satisfactory results are to be secured.

Let us assume that it is desired to increase the efficiency of a given plant. The first step is the installation of necessary recording apparatus. Very few instruments are needed for an ordinary plant, but these must be regularly used and the records reviewed and studied. It is a waste of money and effort and will defeat our purpose to go into greater instrumental refinements than the operator can intelligently understand and handle in every particular.

This we can say unreservedly; every boiler setting should have a draft gauge and draft gauge system capable of instant and constant indication of boiler outlet and furnace draft. Accurate water measuring and coal weighing devices are desirable. The chief engineer of a plant of say 600 horsepower or larger should also possess a standard orsat or gas-handling set, and temperature records and observations should be preserved.

Supposing, now, our plant to be equipped as described. The business of effecting conservation in a steam generating plant goes far beyond a mere experiment by trial of the sources of preventable loss and the making of suggestions for improvement. If improvements are to be made they must be under the direction of a competent individual. This may be the chief engineer or boiler room superintendent, or it may be that an outside efficiency engineer is called in. In any event the individual who is to be responsible for the improvement has a job on his hands requiring, above everything else, tact and good judgment.

Let us take, first, the case of the outside so-called efficiency engineer, who is called in to investigate plant conditions with the object of effecting power improvements. The personality of this man is, by all odds, the first and most important consideration. His work will be a bitter disappointment to his client if he does not possess the ability to advance his technical findings in a way that will call into play the loyalty, skill, and energy of the men over whom he is to have more or less supervision. It is infinitely preferable to engage a man of mediocre technical education and experience, who is possessed of tact and personal likableness, than to employ a more learned but tactless scientist, so far as permanent benefits are concerned. Let us see why this is so.

Outside supervision is decided upon. The engineer assigned to effect the improvements visits the plant and goes over its layout; he questions the operating forces, conducts certain preliminary tests, and perhaps places in the boiler room an assistant more or less equipped with knowledge and instruments. The results of this preliminary investigation is usually a report between 20 and 40 pages long, containing statements of fact as to adaptability of fuel, draft, gas analyses, plant routine, and operating methods; it is apt to contain criticisms with respect to all of these; it may attempt to show the effect of one deficiency upon all the rest. In hardly any instance is the plant fully equipped for first-grade performance. Therefore suggestions are offered to the management, with respect to certain changes or additions to be provided in the equipment, and the reasons are given to support such recommendations. This is all very well. After the management has

INSTRUCTIONS TO FIREMEN

Details

1. On hand fired furnaces. After shaking grates, take scraper and push fires to the rear, leaving bed of hot coals 2" to 3" thick. Throw green coal in front to required thickness, spread lightly in the rear.
2. Maintain level fuel bed at all times.
3. Fires must be cleaned every twelve hours on load less than 2000 KW.
4. Fires must be cleaned every eight hours on loads in excess of 2000 KW.
5. On hand fired furnaces only one fire door may be opened at a time.
6. Weigh and record all coal placed in stoker hoppers.
7. Do not let supply of coal in stoker hoppers fall below level of top of hopper.
8. Keep continuous flow of feed water into boilers.
9. When shifts are changed have feed water at normal level.
10. Blow down boiler every twenty-four hours, starting with boiler #1 at 10 o'clock P. M. Open and close blow-off valve slowly, allowing 2 minutes by watch for complete operation.
11. Operate soot blowers on all boilers three times in twenty-four hours, starting with boiler #1 at 9 A.M. 5 P.M. and 1 A.M.
12. Blow soot blower units from front to rear of boiler, starting with Unit A in first pass, allow three revolutions of the blower element then shut off steam on this unit and operate unit B in a similar manner, etc.

gone over the report it gives the chief engineer a chance to mull it over, and from him it receives back a guarded criticism of the findings. He praises the report faintly, and, because the operating forces have proven themselves loyal and capable in the past, in so far as the management has been able to determine, the effect is to delay constructive action on the programme outlined in the report.

Now, why does the operating engineer look upon the efficiency man with a cold eye? Well, in the first place, when it comes to intimate knowledge of the details of operation, such as likelihood of sudden extreme demands for steam, or the reverse, the operating man knows from experience the situation in his plant, while the outsider cannot possibly get it all. The efficiency engineer, therefore, is at a disadvantage. Very likely the operating engineer will, in his own mind, lay great stress upon some minor matter, while overlooking important phases of operation, and the mere fact that something known to him has not found its way into the report prominently causes him to discount all the rest.

Operating forces are only human, and the spirit of resistance is set up against any suggestions offered by the outsider. Now the technique of operation has a more important bearing on the attainments of high efficiency in boiler practice than any other factor, consequently, unless the efficiency engineer can win the confidence and backing of the operating forces, his work will be valueless. Modern production practice calls for rapid changes in methods, as new and better ways of doing things are discovered. If the boiler room in question supplies a large factory, the chances are that the management and all of the factory department heads are thoroughly alive to the frequent necessity of change. They live in an atmosphere of progress and do not hesitate to make radical changes in the location of machines and methods of handling operations, if these seem desirable. The boiler room is a different proposition. Here the tendency is to refer everything to custom and precedent. The operating men have performed their duties in certain individual ways, and no complaint has heretofore been registered against their methods Why, then, should a change be proposed.

The very first requisite of an improvement is, therefore, ample time in which to effect it. The services of the efficiency engineer are of value to the plant management in increasing proportion to the length of service; that is to say, if the efficiency engineer is to give sixty days time to the plant, his services will be six times as valuable to the management if the time is spread over a period of a year than if it is confined to two months, and three times as valuable over six months as over two. It takes about so long to work out resistance to change, and the operating forces must be given opportunity to accommodate themselves to the presence of one who stands, for the time being, closer to the management than they do themselves.

Granted tact and technical skill on the part of the efficiency engineer, it will still be very surprising if the operating forces are not more or less antagonistic to his presence in the plant for a period of two months or more. When the operating men finally realize that the efficiency engineer does not intend to recommend wholesale discharge, and that he is not in the plant for the purpopse of showing them up, but rather for the purpose of co-operation with them, to the end that they themselves may increase their own efficiency, they will begin to be stimulated by his efforts. If the efficiency engineer has real technical ability, as well as tact, they will begin to respect him for what he knows and for his character.

The process works two ways. The efficiency engineer discovers that his original impressions regarding the plant and the men were incorrect in many details. Real results are finally in a fair way to be attained when the operating man comes to look upon the efficiency engineer as a regular employee. It is then much easier to work together, and the efficiency engineer can set himself to the real test of his capability. This consists in so managing to suggest his thoughts and methods to the operating men that they will beat him to their expression and execution; in other words, they will adopt the thought or suggestion as their own.

At this point, if the efficiency engineer has managed to get the operating men to advance as their own the ideals he is seeking to inculcate, he, to some extent, negatives or deprecates them, the result may be beneficial, in that it may cause the operating men to make every effort to prove the correctness of their views, and since the idea is, as they believe, the creature of their own making, unquestioned support will be given to its successful accomplishment.

There is no question that the mental attitude of the operating force has an extremely important bearing upon the successful operation of the plant equipment. Thus it often happens that, in a plant containing one kind of mechanical stoker in successful operation, that when a new engineer comes on the job, differences will begin to be apparent in stoker operation which can be attributed more to the prejudice of the engineer than to lack of knowledge or ability on his part to operate the equipment properly. It is therefore of the greatest importance that any man, who is set up as an instructor over men who consider themselves already thoroughly trained and competent, should possess infinite tact and good judgment. When such a man overcomes the inertia of bad habits these will inevitably be replaced by the inertia of good habits.

The important thing to remember is that it takes time and much patience to accomplish the desired results. Some managers, it is true, do not have any great confidence in methods such as we have outlined, and, being impatient of results, believe that the quick and sure way to accomplish reform is to perform, at once, a surgical operation by discharging the old crews, or at least their chiefs.

It is the writer's opinion, backed up by the experience of men who have tried both methods, that the best results are not secured by wholesale firing. A new chief and new assistants are at a loss when it comes to detailed knowledge of plant conditions, and the time which it takes to familiarize themselves with

INSTRUCTIONS TO FIREMEN

General

1. Even load in the neighborhood of 10,000 pounds of steam flow per hour must be maintained on each boiler. Bank one or more boilers if necessary to secure the proper load on each boiler in operation.

2. Maintain even flow of feed water. Permit rise of 8 inches in gauge when load drops rapidly, and fall of 8 inches below normal in gauge in case of sudden demands on boilers.

3. For hand fired boilers. Use the spreading method, firing 8 to 10 shovelfulls at a charge, starting from rear and completely covering fuel bed.

4. For stoker-fired furnaces maintain even fuel bed thickness of 6 inches.

5. Go to instrument board after each firing. If necessary adjust damper draft and ash pit draft in accordance with actual load of steam flow obtaining. (See table in paragraph 6).

6. Regulate conditions as follows;

		Pound Hour.				
WHEN;	Flow per boiler is	8000	9000	10000	11000	12000
THEN	(Ash pit must be	1.2	1.4	1.5	1.6	1.8
	(Damper must be	0.03	0.04	0.05	0.08	0.10
	(Fuel bed must be	4"	4-1/2"	5"	5-1/2"	6"

7. Instrument readings must be recorded every 30 minutes on log charts.

8. Steam pressure must be maintained at 150 pounds per square inch at all times.

these details is largely lost. True, they are less inclined to criticize and withhold co-operation, but they are less capable of making helpful suggestions and of adopting the ideas put forth to the actual plant conditions. Unless there is actual insubordination and continuous attempts to hamper the work of the efficiency engineer, it is far better to retain the old men, who will have at the start of their education a close knowledge of the systems, materials, and equipment with which they have to work.

Instruction From Within

In the preceding sections of this discussion, we have considered the case of the outside efficiency engineer who is called in to improve the efficiency of the plant. All that has been said regarding the necessity for tact and good judgment and the use of a little practical psychology on the part of the efficiency instructor applies equally well if there is to be a permanent instructor inside the plant. That there is ample need for constant training and instruction of power plant employees, is a fact generally recognized by experienced engineers.

It is clearly the duty of the management to provide proper training for its employees, and any management which fails to do this is clearly negligent of its duties. Necessarily the means provided will depend entirely upon the size of the plant and the operating conditions. Thus, in a large central station there may be delegated permanent instructors with each shift in the boiler, pump, turbine, and high-tension rooms, on the switchboard, and with the repair gang, whereas in the smaller plant a single individual may act both as instructor and supervisor. Between these two extremes a number of variations are possible. The point should be clearly borne in mind that the expense of such training is small indeed in comparison with the savings which can be effected through the work of well-trained crews. As a matter of fact the savings can usually be made so large that they will cover many times over the expense of one or more high-priced specialists.

The truth must be realized that only by prolonged training can an adult, who has been given his own gait for many years, be brought to form new habits. He may recognize the value and importance of doing things by newer methods. Yet, if all his life he has been accustomed to doing them in a certain way it will take time, effort, and patience for him to change, yet because this change is absolutely essential it should be consciously and patiently striven for, by both instructor and operator.

The value of correct methods is apparent. Thus, boilers, during periods when tests are conducted by experts, give efficiency results which are almost never attained in average daily practice. Granted that the conditions of load and service during tests conformed to normal requirements, the only explanation of the failure on the part of the operating crews to maintain equally good efficiencies is that they do not carry on the work the way experimentors did. Lack of knowledge, and perhaps lack of incentive, are the real reasons for this failure. In very few plants do the firemen receive any training other than a few words of instruction, after which they are left to shift for themselves. As for helpers and coal passers, they are expected to learn by personal observation of the routine work done by others. Such a process of education, if such it may be called, is of entirely too long a duration at its best, and it is extremely wasteful in both fuel and labor.

After training and instruction have been given verbally and by example, until the men have reached a certain degree of proficiency, the time is at hand to standardize operations and to put them in writing. Typewritten instruction cards should be placed in the boiler room. These cards should detail all operations, and the men should be checked up on their knowledge and compliance with the typewritten instructions. Typical cards are shown in the accompanying illustrations. These cards can be worked out for each individual plant, and they are certainly desirable tools for effecting efficient operation.

WATER POWERS OF CANADA

At the regular meeting of the Toronto section of the American Institute of Electrical Engineers, held in the Engineers' Club on Friday, December 19th, a very interesting paper on the "Water Powers of Canada" was read by Mr. H. Harvey, of the Hydraulic Department, Hydro-Electric Power Commission of Ontario. The paper, which was illustrated by lantern slides, presented a summary of the extent of one of the great assets of the Dominion, and outlined some of the extensive developments under way or in contemplation at the present time.

The Maritime Provinces are not so abundantly blessed with water powers as is the remainder of Canada, but while large developments are not possible, there are many smaller powers available for use in the pulp and paper industry and for use in the exploitation of mineral resources. Quebec is very fortunately situated as regards potential water powers, and while large developments have already taken place, the greater portion of the water powers of the province still remain unutilized. There is, at least, 240,000 horse power still available and capable of easy development near Montreal, while the Saguenay River system and Lake St. John are capable of furnishing over 1,000,000 horse power. This, together with other potential water powers near Quebec City, will undoubtedly benefit industry in this vicinity. The water powers of Quebec will be of immense value in the exploitation of the mineral wealth of the province, and particularly so in electro-chemical and metallurgical industries.

The same applies to the water powers of Manitoba and within a radius of 100 miles of Winnipeg; it is altogether probable that large communities, dependent upon electro-chemical and metallurgical industries, will spring up. The fixation of atmospheric nitrogen for the making of fertilizer will undoubtedly be one of the most promising fields for manufacture, since Manitoba is so conveniently situated, as regards the grain-growing section of the country.

The Prairie Provinces have available considerable water power, the Bow River and the Saskatchewan being capable of considerable development, while the farther-north, the Churchill River emptying into Hudson Bay, has over 1,000 feet head throughout its course.

The Athabasca and Peace Rivers, too, are capable of development, but their location in the north country, emptying as they do into the Mackenzie River, which flows into the Arctic Ocean, renders them of value for the future only.

The Yukon and Klondyke regions have many water powers, and some of these are developed at the present time, the power generated being used in the operation of gold dredges.

The Province of Ontario is the largest industrial centre of the Dominion and at the same time is possessed of the greatest natural wealth in water powers. This is particularly fortunate, in that her coal resources are non-existent. The water powers of the province are divisible into four main divisions, the Ottawa River basin, the Great Lakes, the James Bay basin, and the basin tributary to the Winnipeg River area. The characteristics of these four basins vary greatly, and in some of them the results of deforestation, etc., are noticeable. This is particularly true of such rivers as the Grand and Thames, where the character of the river has been changed from one of comparatively uniform flow to one of excessive run-off, of little use for power or navigation. In all, Ontario possesses 5,000,000 horse power capable of development. This figure includes international boundary waters up to the treaty limit only.

In the paper, and in the discussion which followed, the importance of water power development was emphasized, and the necessity of eliminating the importation of the 25,000,000 tons of coal now brought into the country was brought out.

P. W. Ellis, chairman of the Niagara Falls Park Commission, took part in the discussion, and gave some interesting facts relative to the developments in the Niagara district. He also mentioned the extensive plans of the Commission for the making of this district into a national playground. The necessity for the fullest development of the Falls was also emphasized, and in the further discussion which followed that of Mr. Ellis, it was brought out that the probable limitation of the developments at the Falls would not be affected so much by the necessity for the preservation of scenic beauty as by ice removal. A sufficient amount of water during the winter months must flow over the crest to remove this source of trouble.

THE LARGEST WESTERN ICE PLANT

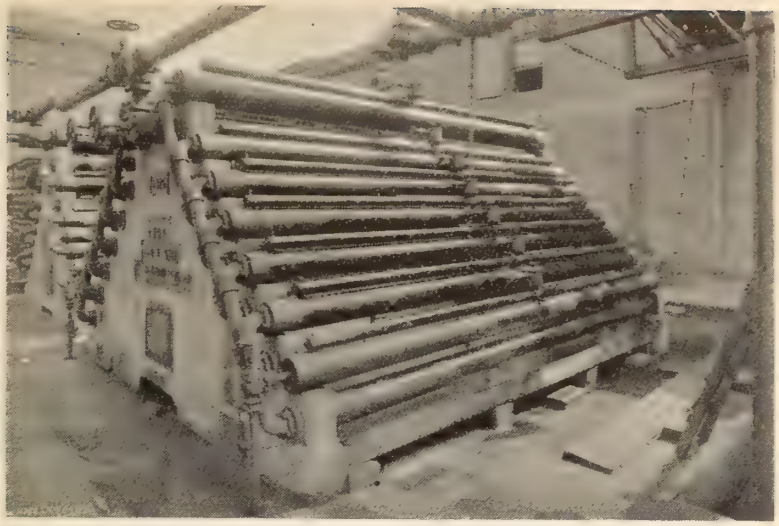
By FRANK C. PERKINS

THE accompanying illustrations, Figs. 1, 2 and 3, show the compressors, ammonia condenser of 8-inch pipe and ice tank of 800 lb. cans, with six control electric crane for lifting 3 cans at a time, as utilized in Denver, Colorado, at the 250-ton ice plant of the Colorado Ice and Cold Storage Co. The writer is indebted to George L. Vail, chief engineer, and Victor J. Azbe, consulting engineer, St. Louis, Missouri, for the photographs and data of this largest ice plant of the West.

It is pointed out that while the full capacity of the plant is 350 tons of ice per day, at which rate it is operated six months in the year, still during the cooler six months about 210 tons of ice is manufactured per day, of which 110 tons is put in storage for summer peak loads.

The boiler equipment includes six boilers, the steam pressure maintained being 130 lb. gauge, two of which are of the B. & W. water-tube type, each rated at 350 boiler-horsepower, connected to an economizer.

There are also two of the boilers of the Parker type and of 411 h.p. capacity each, with a short stack, making it necessary to use induced draft. Running the boilers at rating, a flue-gas temperature of 450 deg. F. was obtained. The last two boilers in the plant are of the Kewanee type, rated at 250 h.p. each and the boilers are hand-fired, the grates being of the Vail nozzle type. The air openings are round, one-half-inch diameter on the lower side of the grate and one-quarter inch at the top and the free air opening is 12.8 per cent. of the grate area. Colorado lignite is used, having a heat value of about 10,000 B.t.u. per lb. It is of the black variety and of higher grade than the brown Texas lignite. The boiler-feed water comes from an artesian well, and this water is excellent for boiler purposes, as it practically contains no scale-forming matter. The condenser circulating water is obtained from a surface well by means of two 6 in. centrifugal pumps directly connected to turbines, each having a capacity of about 2,000 gal. per min. This water is at a temperature of about 54 deg. F., summer and winter. It first passes over the ammonia condensers, leaves at about 75 deg. F., and at that temperature goes to the steam condensers. The characteristic of this water is that it begins to deposit heavy scale at a temperature of about 110 deg. F., so that the steam condensers become heavily coated in a short time.



CONDENSERS.

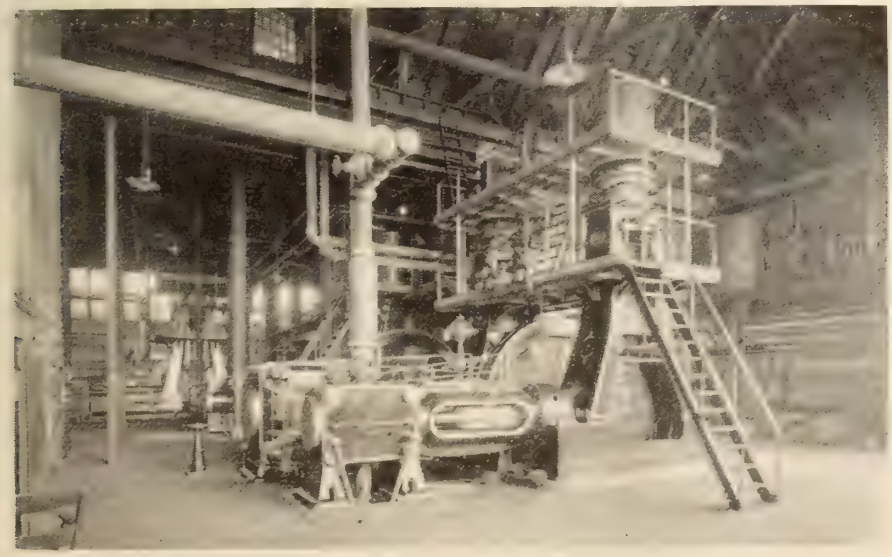
There are four refrigerating machines in use besides the usual auxiliaries. The engine room contains three 250-ton and one 75-ton refrigerating machines, one a cross-compound, one a simple Corliss with single-acting compressor cylinders, and two simple Corliss-driven compressors. The Corliss engine cylinders discharge at atmospheric pressure into steam condensers. These condensers are drums 10 ft. long and 37 in. diameter made of thin gauge copper. When the plant is operated under full capacity, there are 14 of these condensers in use, and since the full plant capacity is 350 tons of ice per 24 hours, then each unit condenses steam for 25 tons of ice each 24 hours.

There are several interesting features in the freezing system for 800-lb. ice blocks, the dimensions of the cans being 23½x12½ in. at the top; 22½x12 in. at the bottom and 7 ft. 11 in. long. As far as effort of pulling is concerned, there is less of it here than is usually encountered with the usual system employing cans of half the size. This is primarily due to the electric crane that is employed. This crane has six controls, one for raising, one for lowering, and the others for moving lengthwise of the tank or sidewise in either direction and no pushing or guiding is required, but while thawing there is no other effort required but controlling the crane.

It may be stated that the electric crane is designed to raise three blocks, or 2,400 lbs. at a time. The pulling is rapid and one workman in one hour will pull from 40 to 48 blocks. The cost of pulling per ton of ice is between two and three cents, and as the plant produces about 100,000 tons of ice per year, the saving by the improved system of pulling 800-lb. crane amounts to $12,000 per annum.

It is pointed out that in the ice tanks there are no ammonia coils, the tank having a double bottom and is fitted with compartments. When a can is inserted into its compartment, there is an inch space between the can and the compartment wall and the brine passes from a brine cooler into the double bottom through a ⅜-in. hole into each can compartment and up through the 1-in. space around the can. The brine level in the tank is maintained exactly at the level of the ice block when frozen and the brine overflows into a compartment, then to a tank, pump and brine cooler finally.

It is of interest to note that for a 50-ton system the tank occupies only a



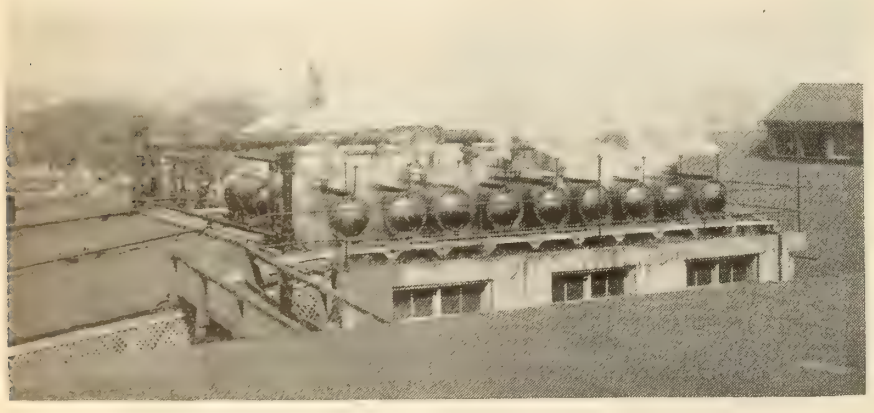
VIEW OF COMPRESSORS.

space measuring in plan 27½x33 ft., while brine is cooled in flooded coolers having 22.6 sq. ft. of surface for each ton of ice, as compared to the usual 100 to 200 sq. ft. employed. The brine cooler for the 50-ton ice tank has 160 tubes 2½ in. in diameter and 12 ft. long. The brine makes eight passages through the cooler, which occupies a horizontal position, and is at all times two-thirds filled with liquid. This liquid does not go over to the machines, as the discharge pressure is always at about 220 deg. F. with a condenser pressure of 150 pounds per square inch.

There is provided for the ice tank circulation of brine several turbine-driven centrifugal pumps operating against a head of about six pounds and the amount of brine circulated per minute per ton of ice is about fifteen gallons, and the temperature difference of brine entering and leaving the brine cooler is from 1½ to 2 deg. On the evaporating side of the refrigerating system the suction pressure maintained is 18 lb., but greater pressure can be obtained easily with more cooling surface. In the ammonia-condensing system there are 29 stands of drip condensers, all being 24 pipes high and 20 ft. long. The plant is provided with condensers made up of 8-in. standard pipes and the ammonia vapor flows successively through 14 lengths of 8-in. pipe, each having 18 ft. of effective length. These 8-in. pipes are interconnected by 2-in. pipes and while the velocity in this condenser is relatively low, good results are obtained in its operation.

There is great interest in the ice storage, which includes two ice-storage houses, one of 4,000 tons capacity and the other, 15,000 tons, the latter being the largest ice-storage house in the country. Its dimensions are 175 ft. long, 60 ft. wide and 60 ft. high, which would mean that there were 30 layers and 500 tons of ice to the layer. The ice is stacked regularly and all the blocks pitched toward the centre of the storage, due to pitching of the floor six inches so as to prevent any danger of the ice sliding toward the walls. The ice blocks lie directly on the floor and at the walls come close to the brine coils, but do not quite touch them. The coils themselves are six inches from the wall and provide for ample air circulation.

It is claimed that in the large storage house there is ten miles of 1¼-in. brine piping to maintain a temperature of 16 deg., this temperature being lower than is usually considered necessary, but the result is that the ice taken out in summer is first-class and the loss is next to nothing.



ANOTHER PORTION OF THE EQUIPMENT.

CLASSES FOR THE INSTRUCTION OF STATIONARY ENGINEERS

THE grading of certificates in Ontario has necessarily aroused considerable interest in educational matters among the engineers of the province. To meet the need for instruction along this line and to give the stationary engineer the opportunities enjoyed by others, the Department of Education has extended the scope of the technical education covered in the night classes, to embrace stationary engineering.

Classes have been established in various centres of the province, and instructors appointed. The subjects covered are those particularly of interest to the engineer in view of the approaching examinations. Thirteen cities have taken up this work and approximately 333 students enrolled. The following list gives the names of the different centres in which the classes have been started, together with the names of instructors and number in attendance:

Brantford, 24 students—Instructor, C. Carriss, engineering staff of the Waterous Engine Works.

Galt, 26 students—Instructor, W. F. Stubbs, engineering department of the Goldie and McCulloch Co.

Hamilton, 37 students—Instructor, J. M. Brown, superintendent the steam plant of the Dominion Power and Transmission Co.

Kitchener, 9 students—Instructor, Mr. Pflug.

London, 22 students—Instructor, D. H. Weir, instructor in science and engineering London Technical School. Mr. D. H. Weir is assisted by various local stationary engineers.

Niagara Falls—This class is in process of organization.—Instructor, Mr. Gisbourne, of the Hydro-Electric Power Commission of Ontario. It is expected that classes will start early in January and forty men have signified their intention of joining.

Ottawa, 40 students—Instructor, John Blezard, of the engineering staff, Department of Mines.

Peterborough.—In progress of organization.

Sarnia, 26 students in two sections—Instructors, W. Wainright in stationary engineering, and M. T. McCordick in arithmetic.

St. Catharines, 54 students — Instructor, Mr. Shields.

Toronto, 37 students, divided as follows: Power plant engineering, junior, 26; instructor, D. Ross, Central Technical School. Power plant engineering, senior, 11; instructor, M. B. Watson, director of engineering Central Technical School.

Windsor.—Instructor, Robert Meade.

Walkerville, 13 students—Instructor, Geo. Bergess.

An analysis of the above figures would tend to show that the stationary engineer was not taking full advantage of his opportunities, whether from lack of knowledge of the classes themselves or otherwise.

In addition to the arranging for these various classes, the Department of Education, through Mr. K. S. MacLachlan, has been instrumental in preparing a syllabus for the guidance of the instructors. The purpose of this syllabus is to aid the instructor in determining the details of the subject matter and to aid in its presentation to the class. The syllabus embracing, as it does, the wide field of steam engineering, covers too broad a field for the complete subjects outlined in it to be taken up in any one class during one winter in night schools. The requirements of stationary engineers vary greatly, and the instructor is given considerable latitude in his selection of subject matter of the greatest benefit to his students.

In case the instructor in any city is definitely preparing men for examination for certificates, he is governing his course according to the Act and its regulations as issued by the Trades and Labor Branch of the Department of Public Works for Ontario.

The Engineering Institute of Canada has made full arrangements for a Dominion-wide convention to be held in the city of Montreal on January 27-29. During the meeting several important papers will be read and discussed; a number of federal and provincial officials will likewise be present, some of whom will give addresses on the activities, past, present and future, of their respective departments, principally in relation to engineering work. The convention will be held in either the Ritz Carlton or the Windsor Hotels.

The Transmutation of Energy

A Paper Read Before the C.A.S.E. at the Brantford Convention Which Deals, in a Clear Manner, With the Various Forms in Which Energy is Made Evident to Us

By C. C. CARRIS

OF all branches of human endeavor none is more urgent in its demands for the accurate recording of facts than of engineering.

The politician may deal with the inconsistencies of human nature, and obtain the assistance of others by his skilful tongue; the merchant can study the peculiarities of his customers, tickle their vanity, and attract them by his display of goods in windows and advertisements; the artist may paint that which is not and yet succeed, if his results are pleasing to the eye, and in many other things appearances are of great importance.

But for the engineer there is no safety in anything but facts. Even though he attains social success through a knowledge of his fellowmen, his actual work, the creation of his skill, must meet the inexorable test of the forces of nature which it is meant to control. He cannot say, "I thought," he must know.

The overloaded bridge will not stand, even though its designer be an eloquent orator. The undersized bolt will not hold no matter how highly polished; the ship will sink if its weight exceeds its displacement. There is no charm that will overcome the forces of nature; their magnitude and direction must be accurately estimated and met by the superior strength of the materials employed.

It is related of one prominent engineer that he was requested to give evidence as to the cause of a disastrous boiler explosion. After much contradictory evidence had been heard, he was asked if he could give the reason for the accident. In reply he stated that the matter was quite simple, the cause of the wreck being merely that the material of the boiler had been subjected to a greater stress than it was able to withstand.

In that simple remark lies the explanation of many superficially mysterious accidents, and the reason that material is subjected to greater stress than it is able to withstand, is usually a lack of accurate knowledge of the facts concerning the stresses to which the structure is to be subjected.

The branch of engineering that comprises the calling of the stationary engineering and his brothers, the marine and locomotive engineers, calls most insistently for facts, and nothing but facts. The reason of this is the very large amount of energy controlled even in the smallest power plant. A very small error in the observation of essential facts may result in the release of this energy with the probability of the death or injury of the engineer and his assistants, and possibly the sacrifice of the lives of many in the adjacent buildings.

Therefore, in addressing a gathering of stationary engineers, who, by the very nature of their calling are trained to deal with facts, it is not advisable to dwell much on fancies or suppositions, but to speak of observed and recorded facts, which constitute the basis of true theory. These facts will be of interest to the stationary engineer, if they deal more especially with the subject of energy, as his whole occupation is concerned with the direction of this peculiar commodity.

One of the fundamental facts of the universe is that energy may be transmitted into many different forms, but that its total cannot be increased or decreased in any way. It may be that further research into the wonders of the universe may reveal some great central source of energy, but present we do not know of such.

The present source of energy for this globe is the sun, which has stored in it a great amount of power, on which our very existence depends.

It is intended in the present remarks to trace some small portion of the sun's energy and to see how much of it is utilized and how much wasted in the various forms into which it is transmitted. The two great sources of motive power that are most widely utilized are the heat contained in various forms of fuel, and the energy stored in water at high levels. Both of these forms are derived from the sun: in some cases many years ago; in other cases from day to day.

The unit by which energy is measured is the foot pound, or a weight of one pound elevated to the height of one foot. The same amount of energy is contained in one pound weight one thousand feet high, as there is in a thousand pound weight one foot high. As every stationary engineer knows, the present practical unit is the horsepower which represents thirty-three thousand foot pounds of work per minute. These two units will be used in the measurement of the various forms of energy considered in the following remarks:

The energy produced by the combustion of fuel was in the first place derived from the heat of the sun, which assisted the growth of plants and gave them the energy to incorporate the various elements available in the soil and atmosphere into the complicated hydrocarbon structures composing wood, peat, etc. Some of this material formed comparatively recently is utilized now as fuel in its original bulky form. The trees and plants that grew many millions of years ago have been compressed and heated, reducing at the same time their bulk and their hydrogen content and forming the fuel we know as coal in all its many forms, from lignite to the hardest anthracite, reaching in some cases the almost pure form of crystallized carbon in black or white diamonds.

The exact process of manufacture of the liquid and gaseous fuels and asphalt to coal oil, gasoline and natural gas, with the hundreds of intermediate grades used for various purposes, is as yet not fully known, but they appear to be derived from vegetable or animal growths that have been subjected to pressure and heat.

The energy contained in fuels is measured in the first place in B.t.u., which is an abbreviation for British thermal units. The B.t.u. represents the heat necessary to raise the temperature of one pound of water from 62 deg. F. to 63 deg. F. The equivalent of the B.t.u. when converted into water work is 778 foot pounds.

The following table gives the approximate B.t.u. and foot pounds available in one pound of various fuels. Taking the height of Niagara Falls as 160 feet, the third column gives the number of pounds of water which would have to pass over the Falls to produce the same amount of energy:

Energy Equivalents

	Foot Pounds	B.T.U.	K.W. Hours	H.P. Hours
Foot pound	1	0.0012861	0.00000037662	0.00000050505
B. T. U.	777.5	1	0.0002928	0.0003927
K.W. Hour	2,655,200	3415	1	1,3410
H.P. Hour	1,980,000	2547	0.7457	1

Fuel—	B.T.U. per lb. Low	High	Average	Foot lbs. per lb.	Lbs. of Waterover Niagara
Wood	8,300	9,100	8,700	6,770,000	42,280
Peat	5,000	9,000	7,000	5,450,000	34,020
Lignite	6,356	7,603	7,000	5,450,000	34,020
Coal, bituminous	13,000	15,000	14,000	10,890,000	68,000
Coal, anthracite	12,000	13,500	12,750	9,920,000	61,370
Carbon, pure	.....	.....	14,544	11,304,232	70,651
Coke	.....	.....	12,600	9,800,000	61,200
Gasoline	19,000	21,000	20,000	15,560,000	97,200
Alcohol, denatured	10,000	12,000	11,000	8,558,000	53,460
Fuel oil	18,000	20,000	19,000	14,780,000	92,340
Acetylene	.....	.....	21,430	16,660,000	104,150
Hydrogen	.....	.....	62,032	48,261,000	301,476

Unfortunately our present methods are so inefficient that only a very small percentage of the energy available is delivered in the form and at the point required.

In an average boiler plant the losses are approximately as follows:

Heat wasted in ashes and coal falling through grates, 5 per cent.

Heat wasted by radiation from walls of furnace and boiler setting, 5 per cent.

Heat wasted directly through stack, including portion necessary to maintain draft, and including steam from the coal and heat wasted by incomplete comb., 22 per cent.

Heat utilized in forming steam, 68 per cent.

Of this steam some portion is used for operating injector or pump for feed-water, and more heat is lost by the radiation from the steam pipes. So that in the case of a steam heating plant using coal of, say, 14,000 B.t.u. per pound, only about 9,000 B.t.u. is delivered to the customer. Assuming the feed-water to be received at 65 deg. F. and raised to 125 pounds steam, it would then contain 1,192 B.t.u. per pound. Deducting the B.t.u. in the water, 33 B.t.u. per pound. We have to supply 1,159 B.t.u. per pound.

Our one lb. of coal of 14,000 B.t.u. should supply about 12 lbs. of steam. We will consider ourselves lucky to get 8 lbs. out of it.

If the water returned from the radiators at 212 deg. the customer will actually receive:

$$\begin{array}{r} 1159 \\ 180 \\ \hline \end{array}$$

979 B.t.u. from each pound of steam supplied, or × by 8 = 7832 B.t.u. from each lb. of coal, an efficiency of about $\frac{7832}{14000}$ = 56 per cent.

Now, let us compare this with electric heating, assuming that we are using Niagara power. The first loss we encounter is due to the turbine efficiency which we can assume is about 85 per cent. The next is in the generator, say, 95 per cent. efficiency; step up the transformer, 98 per cent.; transmission line, 95 per cent.

First step down transformer, 98 per cent., second step down transformer 98 per cent. Multiplying up those efficiencies we get a total efficiency of 72 per cent. The heater itself, if of the non-luminous or low temperature type, has an efficiency of practically 100 per cent. In other words, all the electrical energy delivered to the heater is converted into heat within the building heated. The only source of loss of heat is the infinitesimal amount conducted to the outer air by the entrance wires. In the case of the luminous heater there is also a small portion of the energy wasted, as far as heat is concerned, by being converted into light. How small [illegible] later.

Following up our comparison with steam we find that of every 100 foot pounds contained in the coal only 56 ft. lbs. are delivered as useful heat, whereas of every 100 ft. lbs. of energy contained in the falling water at Niagara, 72 ft. pounds can be delivered as useful heat an efficiency 29 per cent. higher.

A further interesting comparison between steam heat and electric heat is as follows:

1—K.W.H. = 2,655,200 ft. pounds.
= 3,415 B.t.u.

The average price of 1 K.W.H. delivered is about 1¼c. The number of B.t.u. delivered by steam heat from 1 lb. of coal is about 56 per cent. of 14,000/—7,832 B.t.u. To obtain 3,415 B.t.u. as before, we would require about $\frac{3415}{7832}$ — .436 lbs. of coal $\frac{2000}{.436}$ × 1¼c — $57.00 per ton of coal so that soft coal would have to raise to seven or eight times its present price before electric heat could compete with steam heat.

In the matter of cooking the comparison is very different, the monthly cost of cooking for an average family running about $2.00, which would not buy very much hard coal.

Passing on from heating to power, and dealing first with the average single cylinder non-condensing steam plant, under summer conditions we find an average steam consumption of about 34 lbs. per indicated h.p.h. With a mechanical efficiency of 85 per cent., the consumption per B. h.p.h. is about 40 lbs.

In our boiler calculations we have assumed an efficiency of 65 per cent. from coal to steam. The engine under consideration uses $\frac{40 \times 1159}{60}$ × 778 — 600,000 ft. lbs. per minute and produces 33,000 foot pounds of power per minute, an efficiency of 5.5 per cent.

The efficiency from coal to engine shaft is 3.58 per cent.

The work of various engineers in designing, constructing and operating steam plants to produce power from coal is no doubt worthy of praise, but as an economic performance it is very poor. At the present time there is no justification for the operation of any steam plant in Western Ontario for power purposes only, except in the case of those factories such as sawmills, which produce their own fuel as a by-product of their regular processes.

Even in this case careful investigation should be made as to whether some portion of the waste cannot be prevented by change of process and also as to whether the waste cannot be better utilized as the raw material for some other process.

The power plant which is designed primarily as a steam heating plant, including those plants in connection with factories using large amounts of steam for cooking, is in a much stronger economic position.

In fact, steam heating is the most satisfactory and efficient method of heating buildings at present in use. The point to watch in designing a combined heat and power plant is to see that the power plant is small enough so that all the exhaust steam is used for heating. Any excess of heat required during extreme weather should be supplied by live steam. If the power demands exceed the heat demands, the balance of the winter power should be supplied by electricity.

It is not uncommon in factories requiring large amounts of power to see great quantities of exhaust steam escaping unused even in extreme winter weather. Under present conditions this should not be permitted, but the load on the engine should be reduced by the use of motors until no exhaust steam is wasted during zero weather.

Owing to the plan of charging on peak load or connected load, it is cheaper to err on the side of using a small amount of live steam, rather than having too much exhaust steam available.

We have seen that the efficiency of transmission from water to electricity delivered is about 72 per cent. Taking the efficiency of the motors at 87 per cent., there proves to be 62 per cent. of our water power delivered at the motor shaft.

Man's attempts at utilizing electrical energy have, up to the present time, been much more satisfactory than his attempts at utilizing the chemical energy contained in fuel.

A side of the power question that is often overlooked is that coal, besides being a source of heat, is also the raw for the production of useful drugs and dyes and other products. Its ultimate value to humanity for these purposes will be far greater than its power value. We also require it for heating as distinct from power. Now we have a great store of coal in this earth, but it is not unlimited and we know of nothing to replace it. It is essentially a thing to be hoarded and used carefully. We can leave it in the ground like money in the bank, and can draw on it when we wish, either now or thousands of years from now. It will keep, it won't spoil.

But water power is opposite in its properties. Every cubic foot of water passing down the falls expends its energy in wearing away the rocks of the river bed. That energy is gone forever, as far as we are concerned. More water follows it, but the energy contained in that particular weight of water is lost.

It must be used to save it, whereas coal must be left unused to save it.

Not many years from now people will be complaining of the folly of this generation in wishing to retain a water falls as something to look at, while wasting millions of tons of valuable coal to do work that could have been done by the wasted water power.

The third item to be considered is

lighting. Before going into this subject, it is well to inquire, what is light?

Light, as we see it every day, consists of vibrations of the luminiferous ether of such length that they affect the mechanism of the eyes. The longest rays that affect the eyes are those given off a dull red heat. The shortest rays that we can see are the violet. A mixture of these rays give the sensation known as white light. There are also ultra red rays and ultra violet rays, none of these are visible, but they both produce chemical effects and therefore photographs can be made by their use, which proves their existence. The light that is most useful to the eyes lies between yellow and green, but unfortunately in our attempts to produce light of this color we also produce rays of many other colors and also produce a large amount of heat. ,

The most efficient light in common use, the gas-filled tungsten lamps, requires about ½ watt per candlepower. This lamp gives off a quantity of rays up around the violet end of the spectrum; so much in fact that the effect on the eyes is unpleasant unless the lamp is shaded. It also gives off a very large amount of heat. The balance of the power consumed in producing useful light is very small, being about 15 per cent.; an ordinary carbon filament lamp using about 4 watts per candle power only delivers about .2% of the power consumed as light, a plain tungsten lamp about 7 per cent. This can readily be proved by putting a lamp into a fish globe full of water and leaving it there one hour. Measure the temperature of the water before and after.

So if we deliver 42 per cent. of our water power at the lamp, we only get 10.8 per cent. of it as light from a gas filled lamp, 1.42 per cent. from a carbon lamp, and 5 per cent. from an ordinary tungsten lamp. Just think of that for a moment, 1,000 kw. at Niagara Falls equals 50 kw. of actual light in Brantford, or put it another way; a man turning a crank can do about 44 lbs. of work per second or 2,640 ft. pounds per minute—60 watts, or 50 candlepower from ordinary tungsten lamps. With 100 per cent. efficient lamps the same man can produce 715 candlepower. There is room for considerable study and the possibility of making a fortune by the production of a more efficient lamp. There are two general methods in use of producing light, first the highly heated filament; second the luminous vapor, such as used in the mercury arc, and the Moore vacuum tube. It is unwise to prophesy, but the heated filament seems at present to have reached the end of its possibilities. All substances at present known will fuse at any increase in temperature over the 27,000 centigrade now used in the gas-filled lamp.

The luminous vapor system seems to offer the greatest possibilities of improvement, based on the use of high tension current passed through tubes filled with gas at low pressure. In the meantime it is our duty to press for the gas filled-lamp in all suitable locations. The units available are still rather large for house use except in special fixtures, but for general factory, store and street illumination it is the only light to consider.

These remarks have in general dealt with the steam plant only from the point of efficiency. Nothing in them should be construed as reflecting on their reliability, which is over 99 per cent. There are many factories that are glad in cases of emergency to fall back on their steam engine. But this consideration does not justify us in wasting good coal, so long as cheap water power is available.

One thought in closing. It is always repugnant to the mind of the intelligent man to think that after this life comes death in both mind and body. On the other hand, his mind rejects the idea of absolute idleness for all eternity, except during the flash of time called life.

May we not hope that even as we transmute energy into various useful, but different forms, so will the Chief Engineer of the universe transmute our vital spark of energy into forms of usefulness, of which at present we have no conception.

The Transmission of Power by Means of Gas

The Following Article Published Through the Courtesy of the "Times Engineering" Supplement Gives a Correspondent's Plea for the Use of Gas in the Transmission of Power

A COMPARISON WITH ELECTRICITY

ONE of the objects aimed at by the proposal to provide a general supply of electricity distributed from 16 huge generating stations is to get rid of the cost of conveying coal to each individual factory. But why is it taken for granted that electricity is the only agency whereby the carriage of coal can be eliminated? Why has not the possibility of using gas for the purpose been at least considered.

The idea of conveying energy to great distances by means of electricity is familiar. It looks a simple matter to string a wire to any distance and send power along it in any desired quantity. But where the distance is great and a large amount of power is required, the "wire" is apt to assume formidable proportions, and the loss by the way is by no means negligible. Let us take as a definite example the transmission to London of, say, 240,000 kw. generated in the Yorkshire coalfield, some 173 miles away.

Electrical Transmission

The size of the conductors and the efficiency realized will obviously depend on the mode of transmission adopted and the voltage at which the current is delivered to the line. As regards method, there is little doubt that the transmission would be on the three-phase system. In America and elsewhere, long distance transmissions at potentials of 100,000 volts and more have been in operation for years, but in this country (England) the distances are short, and the voltages employed (so far as the writer is aware) do not exceed 30,000. For a 173-mile transmission, it is practically certain that the voltage would be higher than 30,000, and not more than 100,000, and it will be instructive to see how the transmission works out in these two extreme cases.

If the current density is 1,000 amps per square inch, the drop will be 7,330 volts per line, or, say, 12,700 volts between phases. With an initial potential of 30,000 volts, the terminal pressure will be only 17,300 volts, and the loss in transmission 42.3 per cent., which is out of the question. With a current density of 500 amps., the drop between phases will be reduced to 6,350 volts, or 21.2 per cent., giving a terminal pressure of 23,650 volts. The loss is still very high, but, at the voltage stated, it could be reduced only at the cost of an enormous expenditure in copper. To deliver 240,000 kw. in London at 23,650 volts, the current would be 6,518 amps., requiring (at 500 amps. per square inch) 13 square inches of copper per line, or 39.1 square inches in all. If the conductors were solid, each would be 4 1-16 inches in diameter—a very respectable "wire." At nine tons per square inch per mile, the three lines would weigh 352 tons per mile, or about 61,000 tons in all. Working, however, at 100,000 volts, the current would be reduced to 1,766 amps., the united area of the conductors (at 1,000 amps. per square inch) to 5.3 square inches, and their weight to 47.7 tons per mile, or 8,250 tons in all. The drop would then be 12,700 volts, or 12.7 per cent., and the current would be delivered at 87,300 volts.

Cost of Gas Pipe Line

Now, let us glance at the other alternative, and, instead of transmitting the energy in the form of electricity, carbonize the coal at the pit's mouth, pipe the gas to London, and generate current there by means of gas engines. The amount of gas required to yield 240,000

kw. will be about 5,000,000 cubic feet an hour, or 84,000 cubic feet a minute. A 24-inch steel pipe will convey this gas, with an initial pressure of 300 lbs. per square inch. The wall of the pipe will be 5-16 inch thick at the compressor end, reduced to ¼ inch as the pressure drops. It will weigh from 160 to 200 tons per mile, or about 32,000 tons for the whole line—just one-half of the weight of the copper required to transmit the same amount of energy at 30,000 volts, or four times that for a 100,000 volt transmission.

But the price of electrolytic copper to-day is about £125 per ton, while steel tubes can be bought for, say, £30. The metal required for transmission by gas will, therefore, cost less than that for electric transmission, even at 100,000 volts, and only about one-eighth of that required at the highest pressure which has yet been employed in this country. Aluminium might be used instead of copper, but this metal, also, is more expensive than steel.

Now, as to the loss of energy in a scheme of gas transmission. To compress 84,000 cubic feet a minute to 300 lbs. per square inch will require some 21,726 i.h.p. If the mechanical equivalent of the 240,000 kw., viz., 321,674 h.p., is added to this, the total becomes 343,400 h.p. Of this total, only 21,726 h.p., or 6.3 per cent. is expended in the transmission, as against 21.2 and 12.7 per cent. respectively with electricity.

Storage and Load Factor

But there is yet another factor to be taken into account. Until there is a practicable means of storing electricity on a large scale, the whole of the generating and transmission plant—boilers, engines, dynamos, transformers and line—must be capable of supplying the maximum demand at any moment. Gas, on the other hand, can be easily and cheaply stored, and so may be generated and transmitted at a uniform rate throughout the 24 hours, the fluctuations in consumption being taken care of by storage at the delivery end. If, for instance, the load factor is 50 per cent., the generating and transmitting plant need be capable of furnishing and conveying only 42,000 cubic feet of gas per minute. The cost of this plant may, therefore, be reduced by one-half, and its advantage in point of cost over electricity will be doubled.

Coal Economy

There remains to be considered the question of coal economy. If it were merely a case of generating electricity for use in the neighbourhood of the power station, the actual consumption of coal to drive the dynamos might be less with steam-engines than with gas power; but where the electricity has to be conveyed a long distance, the losses in the conductors and in the transformers must be set against those in the manufacture of gas, and the weight of coal required to furnish a given amount of power at the far end of the line will be practically the same in both cases.

But while the consumption of coal is approximately the same for both modes of transmission, there is a vast difference in what is obtained from that coal. For, whereas in the one case we get power, and power only, in the other we receive, in addition, from every ton of our coal well over half a ton of coke, several gallons of tar, and from 16 lbs. to 20 lbs. of ammonium sulphate. So valuable are these "by-products," that the question of carbonizing the coal used to generate electricity in large stations has been seriously discussed. A satisfactory gas-engine of over 5000 h.p. has, however, yet to be built, and at present, for large power stations, the steam turbine holds the field. A new factor, however, is introduced by the generation of gas from coal of all grades at the pit's mouth, and the substitution of the conveyance of gas under pressure for the transportation of coal. The economies thus effected would go a long way towards making the gas-driven generator a commercial possibility.

Supply of Heat

So far, the transmission of power has been considered. But in many factories, and every home, large quantities of heat are also required, and although heat can be conveyed in the form of electricity, the process of converting heat into electrical energy and the latter back into heat is wasteful in the extreme. If the 240,000 kw. were required for use as heat, that heat could be obtained from 30,500 cubic feet per minute of gas of 450 B.Th.U. net, as against the 84,000 cubic feet required to generate the equivalent in power. So far, then, as the supply of heat is concerned, the superiority of gas is overwhelming.

No doubt great economies might be effected in the manufacture of gas by generating it in the coalfields in large works on the most modern lines, instead of in a multiplicity of works of all sizes and types, most of them occupying expensive and highly-rated sites, scattered throughout the length and breadth of the country, and having to transport every ton of their coal. The cost of bringing to London the coal used by the Gas Light and Coke Company was given last July by the Governor to the President of the Board of Trade as 12s. 9d. a ton. For last year's consumption, this would work out at £1,187,000, equivalent to 10¾d. per 1,000 cubic feet of gas sold. The money spent on the carriage of one year's coal would have paid for a main large enough to bring from Yorkshire the whole of the gas made by the company during the year.

The potentialities of gas transmission being so enormous, it is strange that gas has not been considered as an alternative to electricity in connection with the vast schemes of power supply which have recently been brought forword. This omission is the more surprising when it is remembered that compressed air has long been used as a medium for the conveyance of power, and that something like 150 times as much energy can be transmitted by a gas main as by the same pipe conveying air. The possibility of piping gas to long distances is hardly realized in this country, although in the United States it has for many years past been carried upwards of 200 miles, in the case of natural gas, and 35 miles or more in that of coal gas.

Leakage and Condensation

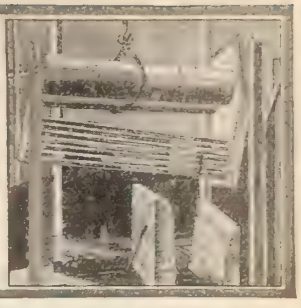
When the question of the long-distance transmission of gas was first mooted here, grave doubts were entertained on the score of leakage and condensation. When the first long-distance mains were laid in the United States gas was cheap, the jointing of pipes to resist high pressures was not understood, and the losses by leakage were enormous. But the art of pipe-jointing has made great strides since then, and the leakage from the later American pipe-lines is said to be inconsiderable.

The fears expressed as regards condensation were based on the assumption that the gas employed would be of the pre-war illuminating type, and that its heavier constituents would be thrown down in such quantities as seriously to reduce its calorific value. Recent experiments, however, in the compression of ordinary coal gas for motor vehicles show that at a pressure of 300 lb. the loss of calorific value is only from 3 to 4 per cent. Any such loss might be prevented by the use of one of the so-called "fuel gases," but for economical transmission over long distances it is essential that the gas should be of low denity and high calorific value. It is probable, therefore, that the long-distance gas would be of the ordinary coal-gas type, made, however, without reference to those standards of illuminating power for the attainment of which the consumer has been so heavily taxed in the past.

It does not follow that there would be no field for "fuel gas." There is a large demand for power, light and heat within a comparatively short radius of the coalfields; and the conveyance of the poorer gases over short distances is distinctly a commercial possibility. It should be remembered, moreover, that any general displacement of coal by gas would involve the production of coke in quantities far exceeding the demand for metallurgical purposes, and for this coke the manufacture of fuel gas would supply a profitable outlet.

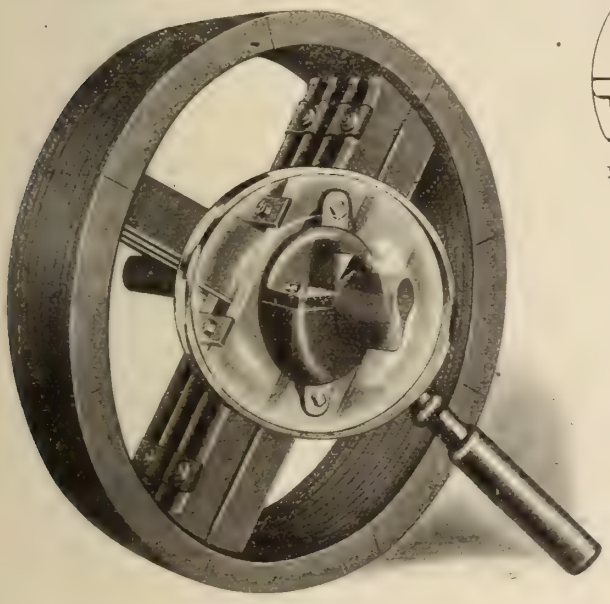
The Link-Belt Company are extending their Belmont Foundry at Indianapolis. The extension virtually consists in the completion of their new furnace buildings Nos. 7 and 8, which will be of 15-ton capacity instead of 10-ton, like the present furnaces. They are also purchasing the necessary machinery, such as rolling mills, sand blast and other foundry equipment needed to take care of the additional capacity. The building will be about 70 feet wide by 400 feet long.

NEW POWER PLANT EQUIPMENT



ANTI-SLIP DEVICE FOR WOOD PULLEYS

Slippage of pulleys on live shafting is one of the many troubles that the engineer has to contend with. The loss of efficiency in this way is often considerable. Where heavy loads are placed on a certain pulley it is very difficult to prevent slip. The illustrations herewith show a simple device that the A. Bernard Industrial Company, Montreal, have designed and placed on the market.

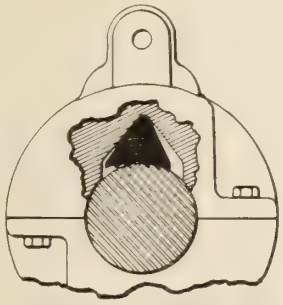


The device may be attached to any make of wood-split pulley, and consists of three distinct pieces held together with two standard machine screws. The recess in the collar and the dog are so designed that the slightest tendency to slip causes the dog to take a firmer grip on the shaft, thus preventing slipping.

PRIMING REMEDIES

A general indication leading one to think boiler priming is taking place is the violent agitation of the water in the gauge glass, together with its muddy and discolored appearance. Sometimes this level will record as much as two inches of difference within the space of a few seconds; sometimes disappearing below or above the glass altogether. If it is thought that fluctuation of steam demands is giving rise to the trouble close down the boiler stop valve a little.

The anti-priming pipe, usually found in Lancashire or Galloway type boilers, is a slotted pipe fixed inside the boiler towards the top, cast in sections and bolted together. This pipe should be at least three-quarters the length of the boiler, and the area of the slots at least equal to the bore of the steam valve.



METHOD OF OPERATION.

Whenever the boiler is opened up for cleaning or repairs, these slots should be examined for corrosion and reduction of orifice area, as priming trouble may be due to this cause. One peculiar feature of priming is that the trouble may be apparent in a more or less greater degree with the type of labor employed in firing, thus proving that the manner in which the boiler is fired is an important factor in this respect. The thinnest film of grease clinging to the water within the boiler will sometimes give rise to priming, hence care should be taken to eliminate this from the feed-water. Boiler compositions introduced for the purpose of reducing scale must be used sparingly and in small quantities at a time. A day's supply should not be injected within a few minutes by means of the boiler pump or injector; instead, it should be spread over a whole day's supply of feed-water. Priming due to a high-water value can be remedied by lowering the water line, but in this expert advice should be taken in order that the danger limit is not reached.

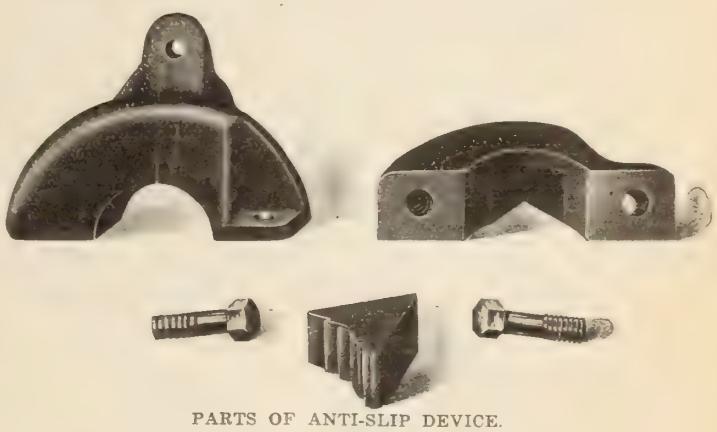
WATER POWERS OF B. C.

Continued from page 7

At No. 2 station there are also step-up transformers, from 2,200 volts to 22,000 volts. This enables plants Nos. 1 and 2 to be run in parallel for transmitting power to Rossland, Trail, Nelson and Silver King mine. The longest distance over which current at this voltage is transmitted is 32 miles.

Plant No. 3. Kettle River

The Kettle River plant, known as Plant No. 3, or the Cascade Forks. At this point the river flows through a gorge, with a series of rapids and falls, providing a natural head of 120 feet in a distance of about one-half mile. A dam at the head of the gorge raises the water level some 36 feet. From the dam the water is conveyed by 700 feet of open-rock cut and 400 feet of tunnel to the pipe-line intake; thence to the power house in a steel pipe 7 feet in diameter. The head developed is 156



PARTS OF ANTI-SLIP DEVICE.

The generating equipment comprises three units, each of a 1,300 h.p. turbine, consisting of two 39-inch horizontally mounted runners, direct connected to a 750-kva., 3-phase, 60-cycle, Canadian Westinghouse generator. Speed of the units is 400 r.p.m., and control is by Escher-Wyss mechanical governors. Two 45-kw. exciters are provided. Current is generated at 2,200 volts and stepped up to 22,000 volts for transmission to sub-stations at Grand Forks, Phoenix, Greenwood and Boundary Falls, the last named being 28 miles from No. 3 Plant.

The Transmission of Power

IN this day of electricity we are somewhat prone to consider it the only available means of transmitting power to any great distance, and we neglect at times consideration of other means which might prove both feasible from an engineering standpoint and profitable in a commercial sense. The utilization of our Western lignites has provided us with a number of very interesting problems, and among these is the finding of an outlet for the gas resulting from carbonization, now on a commercial basis. The burning of the excess gas under boilers, the generation of electricity and its transmission to distant points might prove possible but the resultant efficiency would be limited.

Great Britain has a somewhat analogous problem on her hands at the present time, and the erection of huge central stations at the mine mouth is seriously being considered. It is proposed to burn the coal under boilers and to transmit electrical energy to the surrounding industrial centres. This scheme, or solution of the problem, does not suit a correspondent of the London *Times*, who suggests an alternative scheme for the transmission of energy which has a lot to commend it. In brief, he proposes that the coal be coked and the resultant gas be transmitted to the various centres which would otherwise utilize electrical energy. The gas, according to his figures, could be transmitted for less power loss than electrical energy, and for less capital expense. Instead of the electric motor internal combustion engines would be used, and the overall efficiency should be materially greater than the combined steam prime-mover and electrical system.

Another advantage would be found in the use of gas for metallurgical and other heating purposes, and the heat units made available from a given amount of coal would be greater than if electrical transmission were used.

The coking of coal, or the carbonizing of lignite, in itself tends to conservation since valuable by-products, ammonia and coal tar compounds, are recovered. In the case of England, a further step could be contemplated and any excess coke over and above that required for metallurgical and other industries near at hand could be completely gasified and the gas resulting transmitted in the same manner.

The suggestion is a good one and well worthy of careful consideration. It would seem to be feasible in certain cases in our Western Provinces and in its entirety might be an alternative to the briquetting of lignites as well as an outlet for the gas formed if the lignite were carbonized and briquetted.

A Much-Misunderstood Term

TERMS of a semi-technical and semi-commercial nature are in current use, which are very imperfectly understood, even by those who should be absolutely clear on the matter. A typical example of this is much in evidence of late in connection with the Ontario Government's Stationary Engineers' Act. For the purpose of grading certificates of competence, and also of grading the relative importance of different plants, a basic unit of power must be adopted. The natural factor to use is the capacity of the boiler, and this is expressed in terms of boiler horsepower. It is this latter expression which leads to so much confusion.

To the general public, horse-power is a familiar term. They know it as a measurement of their car's capacity. They have heard it spoken of in connection with the locomotive that draws them from town to town, the ship that carries them across the lakes and oceans, the aeroplane, etc. The stationary engineer knows it as a measurement of his engine's capacity. The technical engineer, when he thinks of horse-power, recognizes it as a measurement of the rate of doing work. That is 33,000 foot lbs. of work **per minute.** When the term is applied to a boiler nobody seems to be very clear as to what it means, and long misuse has clouded the meaning more than necessary.

Both engine and boiler makers found it necessary, when marketing their wares, to have a simple way of explaining their rating to prospective buyers. Engine builders for some time used a rating based on the circular inches in the engine cylinder, and called this nominal horse-power. This was so far from being a measure of the engine's capacity for doing work that it was soon discontinued, and the indicated horse-power rating was adopted. The boiler-maker needing a rating for his wares, designated his boiler as being of so many horse-power. To determine this, a certain number of square feet of heating surface were allotted to produce one horse-power, this number of feet divided into the total heating surface being the boiler rating. This was a step towards a standard, but unfortunately every maker used a different divisor, usually taking one that would give the highest rating to the boiler. Apart from this,

the rating did not, and does not convey much meaning to the average commercial user. For instance, two users may have each a 100 H.P. engine. One is compound condensing, and uses 18 lbs. steam per horse-power per hour. The second is an automatic slide-valve and uses 30 to 35 lbs. steam per horse-power per hour. Now, if they go out and ask for a 100 H.P. boiler in the open market one will get a boiler inadequate to his needs. Recognizing this, experiments were made by the American Society of Mechanical Engineers, who determined that a boiler horse-power should be the capacity to evaporate 34½ pounds of water at 212° F. to steam at 212° F. per hour. This is a definite performance, involving the expenditure of a definite amount of heat, which gives a definite amount of energy available, and horse-power is energy expended at a certain rate. Now, obviously as fuel is the medium to supply the heat, the evaporation depends on the amount of fuel burnt per hour. Therefore, if a prospective buyer knows the grate surface he can form a fair idea of the evaporative capacity of the boiler. A very closely approximate rule is to take the area of the grate and multiply it by three. For instance, a 60-inch boiler will have a fire grate 5 x 5, and multiply ing by 3, gives 75 H.P. The Ontario Government standard is 34 pounds of water from and at 212° F. per hour. They also give 15 square feet of heating surface per horse-power for a horizontal boiler, and variations from this for other types. However, horse-power, based on heating surface, is only useful as a commercial term. It is the evaporative capacity of the boiler that counts, and, while the heating surface has something to do with this, the amount of fuel that can be burnt per square foot grate per hour is the real governing condition.

A Real Mechanic For a Day

OH, I like a-hangin' round the house the week past Christmas time; the feelin' that camps in my chest is powerful nigh divine. I love that season of the year, by gum, I surely do—it makes me be a kid once more and makes old things come new.

In that there season of the year I get my saw and file, I get my hammer and the glue, I hatch also a smile, and then I gather spikes and tacks, a daub of paint what's red, and tell the kids to come along, I'm fit to go ahead.

And that procesh then starts to come in anguish and in woe; I have to put a spine in new and straighten out a toe—and put a neck beneath a head, and sprout a brand new leg, and make a hen look like as though she'd squat and mold an egg.

And what are all these wondrous things I operate on now—to chase the wrinkle and the scowl from out the childish brow? Why, just the Christmas stream of junk that's built for hours of play—the elephants that thrive an hour, the dolls that live a day.

I put new ears upon the horse, new wheels upon the carts, the Noah's Ark calls forth in grief for sixteen brand new parts.

Oh, in them hours I do rare tricks that sawbones wouldn't try—I carve a leg from out a slab, of beads I mold an eye. Ah, yes, I am a man of parts, smart lookin' to the child; he glories in my stone age craft and in my art so wild. I am a genius for a day, real wheat without the chaff, as I plan new noses for the pigs, new legs for the giraffe.—ARK.

The street railway company in Spokane, Washington, uses a tower for its repairmen that is operated by air pressure. An air cylinder, ten inches in diameter and seven feet long, is connected with the air-brake system of a steam car through control valves located in both ends of the vehicle. The air pressure secured is used to raise and lower the mechanism. Two men can be supported for twenty minutes. For jobs which take a longer time, chains are used to take the weight off the cylinder.

Smile

SMILE—Every time you get the chance—it is the chance smile that wins.
SMILE—If you are thin—laugh if you are fat—and if you're neither—just grin.
SMILE—At hard luck—the fates may think you like it and quit.
SMILE—And never let the sun set on your troubles—set on them yourself.
SMILE—At the past and you can grin at the future.
SMILE—While you are awake and you will laugh in your sleep.
SMILE—When you fail and you will die laughing at your success.
SMILE—When you are mad—and try to frown when you are happy.
SMILE—At a fifteen and it will look like a dollar.
SMILE—If it kills you and you will die with a grin on your face.
SMILE—Every time you think of it and you will soon get the habit.—*"Under Cover."*

Australia Considering Alcohol as Fuel

THE question of growing crops for the production of alcohol to be used as liquid fuel has been under discussion at an agricultural conference in Australia recently. It was stated that in a few years liquid fuel, as at present used, would be exceedingly scarce, and the world would have to turn to alcohol for motive power. The ordinary crops were too expensive to raise for their use in the manufacture of alcohol for industrial purposes and the only one at the present time which seemed to offer much promise of success was sorghum. While this is true of crops in commercial cultivation, another source of supply might well be available in Australia. The Commonwealth of Australia Institute of Science and Industry has been carrying out experiments with the object of producing commercial alcohol from the prickly pear. If this can be done, there is a vast field to be exploited, and in addition to it benefiting from the manufacture of the spirit, Australia will have found a means of checking the spread of the greatest of all vegetable pests. At present there are nearly 23,000,000 acres covered by the prickly pear, an area greater than that under crops. It is estimated that the pest is spreading at the rate of 1,000,000 acres a year.

ABOUT TIME.

The Operators' Point of View

RE GRADED CERTIFICATES

The Editor,—"Justice," in answering my letter which appeared in your issue of November 20, puts an entirely different meaning into his reply, which appears in your December 5 issue. No doubt there are dubs in the engineering profession as well as in other walks of life, but it is very seldom that a man is raised to the position of chief engineer in a plant of any importance unless he has proven to the management that he has qualifications which entitle him to consideration. Although there are to my knowledge lots of men who have charge of two boilers and possibly an engine, who have not much engineering ability yet are holding down jobs that would come under the definition given by "Justice." Now I really do not think that "Justice" would care to be the man to succeed one of these men if they were compelled to go up for examination and were found not to be educated sufficiently to pass. If I am correct in this surmise I have no hesitation in withdrawing the name that I wished on him. In conclusion to "Justice" No. 1 I would say: Do not become discouraged. There is plenty of room at the top—be prepared.

CHIEF.

To Justice No. 2

The Editor:—We are getting results. My impression was that the Engineers were just holding their breath, waiting to hear what the other fellow had to say. In this surmise I have been correct, for we are having lots of correspondence. New blood has appeared. Now as to our new correspondent, Justice No. 2. my learned friend has waded in pretty deep, and I am a little afraid that he may find the going pretty hard if he is not more careful in his statements, to wit. Have not the men who are in charge of plants of unlimited capacity proved that they are qualified to hold down their positions. The fact that they are holding their positions is more conclusive evidence to my mind than if they had set down and passed the highest examination that the British Board of Trade could have designated, or the naval authorities would have asked for in an examination for chief engineer on the latest type of Dreadnought. And again, the managers of commercial industries in these days of strong competition are not altogether pin heads. They are not allowing a non-producing department like the power plant to be long under the supervision of a chief engineer, who, to [illegible] correspondent, are bluffs. Bluff would have been a good name for our friend to have assumed.

Now, just to correct any doubts as to where I stand, Justice No. 2 need not be at all alarmed. When the times comes, I hope to be up with the rest of the boys, ready for my examination and with a just hope based on my experience, and also to Providence that I was fortunate enough in my young days to secure an education that will be of sufficiently high enough grade to give me an excellent chance of securing a first-class certificate. My plea was and is for the man who, by perseverance and determination based on an ambition that any man should be proud of, have overcome all obstacles and attained a position in charge of a large plant. I have one such man in mind at the present time in charge of one of our largest plants, a man who can talk very intelligently on engineering subjects, who I know could not pass the examination for a second-class certificate. Yet in every way he is an exceptionally good man, can handle men and knows when he is getting good results from his plant. The writer of this has in his employ a staff of about 20 men. One of these men could sit down and pass any examination that the examiners could put before him. Yet he would not be a first-class engineer then. He is a wizard for engineers' examination questions, but lacks all other qualifications that are necessary in the making of a man to handle large plants economically and efficiently. No, my friend's ability to figure out the problems that the examiners will place before you not alone suffice you, even if you are fortunate enough to secure the coveted certificate. For the paper will not make the man, and some of those poor unintelligent employees who are so easily deceived by those chiefs, who you say are at the present time being bluffed, will soon call your hand if you are fortunate enough in putting one over on them and securing a position in their plants. Yes, it is justice we want and it is justice I expect we will get. 70 per cent. or less if a man's experience calls for anything, and I have confidence enough in the integrity of our examiners to know that they will not turn any man down, who, like the man I referred to above, has all the earmarks of a first-class man, but lacks the education to work out problems in higher mathematics.

CHIEF.

GRADED CERTIFICATES

The Editor,—I have been much interested in the correspondence appearing over the name of "Justice." I am afraid he does not know the meaning of the word, at least so far as the grading of the stationary engineer is concerned. To my way of thinking, if he has had the experience, he should be granted a first-class certificate, that is, a man with wide experience, one who can clear the ground, put in the foundations and set up his power plant in accordance with the Government regulations, is deserving of a certificate, although he may not have had the school training that the young engineer has to-day. Why make him take a back seat because of his not having all the formulae in his head.

I know I for one could not sit down and figure out the horsepower of a boiler without a handbook, and yet this year I figured out and set up a boiler plant of 800 boiler horsepower which is giving the best results.

I have worked my way from a fireman to the position of engineer, machinist, and machine shop foreman, and now I have to lay down my engineering tools because I cannot compete with the young engineer of to-day. I doubt if this man "Justice" could tell you which end of his engine is running the fastest.

Now, I am not one of those bluffers, but, according to the law of this country I will not be able to obtain a first-class certificate, and there may be a good many more like me. Let "Justice" consider the old engineer who has had twenty-five or thirty years of the trials of the boiler house and engine room without ever having to pull his fire.

The Central Technical School, Toronto is holding night classes, free of charge, for the sationary engineer. The classes are divided into two grades, junior and senior, and while both classes have covered half their allotted work for the year, registration is still open to those who care to take the balance of the courses, and as the last half hour of every lecture is usually spent in the general discussion of practical problems and in question and answer discussion, in which students and instructor take equal part, the classes become a valuable clearing house for information, whether or not those taking the course are preparing for examination. Next year it it the intention of those in charge of this work to organize the night classes into a systematic three years' course, fitting in with the new regulations of the Board of Stationary Engineers. The first year course will cover all technical and theoretical work required for 4th and 3rd class men. The other years will cover one class each. The scope of the instruction carried on will be considerably greater than that required by the regulations.

SOME ELECTRICAL DATA

By J. E. McCormack

TABLES of equivalents in electricity generally consist of statements as to the amount of energy or capacity represented by the terms given, but here is something a little different.

It is hoped that this will be an aid in comprehending some of the various electrical terms used in practice. Here goes!

A cell is a chemical generator of electrical energy.

A battery is a combination of two or more cells.

A primary cell or battery is one in which the electrical energy is developed by direct chemical action.

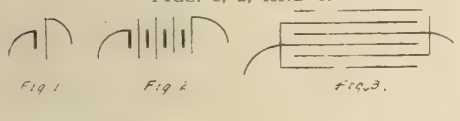
A secondary cell or battery, more often spoken of as a storage or acumulator cell or battery, is one in which the passing of an electric current through it causes chemical charges which render it capable of receiving, retaining and re-developing, a certain amount of electrical energy.

An element (electrically speaking) is the active electrode of a cell.

An electrode is a conductor by which a current enters or leaves an apparatus.

The electrodes of a primary battery are the plates of metal or other substance

FIGS. 1, 2, AND 3.



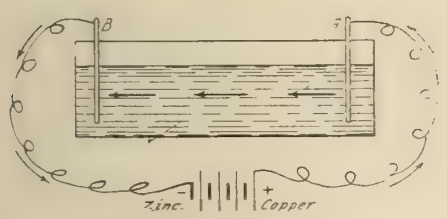


FIGURE 4.

immersed in the liquid. The zinc plate is called the generating electrode and the other plate the conducting electrode. The latter is usually made of carbon, copper being the next most commonly used.

The poles of a battery are the parts of the electrodes which project out of the liquid.

The fluid in a battery is called the electrolyte and in primary batteries is referred to as the exciting fluid or electrolyte.

The terms pole or terminal apply to the ends of a break in any electric circuit.

The negative pole, terminal or plate, is the one by which the current returns to a generator or leaves an instrument.

The positive pole, terminal or plate is that by which the current leaves a generator or enters an instrument. It is the opposite or converse of negative.

The anode is the electrode by which the current enters an instrument (or a battery).

The cathode is the electrode by which the current leaves an instrument (or a battery).

Fig. 1 represents the symbol for a single cell.

Fig. 2 represents the symbol for a number of cells joined in series to form a battery. The short thick line represents the zinc or negative (—) pole. The longer thin line represents the copper or carbon forming the positive (+) pole. Similar symbols are sometimes used to represent condensers but owing to the essential difference in their use there need be little confusion in this double use, but Fig. 3 represents a symbol often used for indicating condensers and which is free from the above objectionable feature.

Electrolysis is the decomposition of a chemical compound by the electric current. Fig. 4 represents a vat containing a solution, the solute of which is undergoing electrolysis by the current from a four-cell battery.

The internal circuit is that part of the circuit within the battery. The external circuit is that part of the circuit outside the battery and extends from the copper at one extremity of the battery and through the wire (conductor) to A, thence through the solution to B, thence through the other conductor to the zinc plate at that end of the battery.

In Fig. 4, the arrow heads indicate the flow of the electrical current. By referring to the definitions for Anode and Cathode given above, it will be seen that with regard to the internal circuit the zinc element of the battery is the anode of the internal circuit; the copper element being the cathode. As regards the external circuit, however, it will be seen that the electrode A being the one by which the current enters the solution is the anode of the external circuit, B being the cathode. As electrolysis calls for a considerable amount of electricity, and as this is more cheaply produced by mechanical than by chemical means, batteries are not used nowadays for effecting electrolysis on a commercial scale and therefore the terms anode and cathode are in practice seldom used now with reference to the internal circuit of a battery, yet is used in that connection just often enough to occasionally confuse or puzzle the novice to whom this point has not been explained. These terms (anode and cathode) are now most commonly applied to plates or rods attached at the ends of a break in an electric circuit such as A and B in Fig. 4, the corresponding terminals in an electro platers' vat, or the carbon rods used in cutting metals by electricity. The terms are also used in X-ray work, etc., and

FIG. 5.

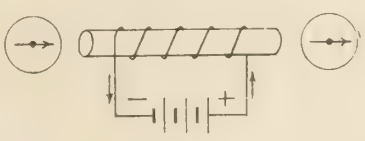

FIG. 6.

always, when applied to external circuits, in this way the anode is the one conected with the positive terminal of the source of current and is the one by which the current enters the vat or other object.

The zinc plate of a primary cell is spoken of as the negative, minus (—), or south, pole or terminal. It will be seen by Fig. 4 that it forms the anode of the cell but that an attached electrode B is the cathode of the external circuit.

The carbon or copper plate or rod of a cell or battery is spoken of as the positive, plus (+), or north, pole or terminal, and it will be seen by Fig. 4 that, while it forms the cathode of the cell, an attached electrode A is the anode of the external circuit.

In the ordinary dry cell the binding

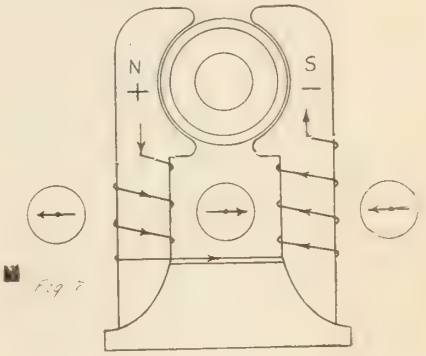

FIG. 7.

post in the centre of the top of the cell is the positive or plus terminal, the element being carbon.

In cells the carbon or copper = plus = + or positive and an electrode plate or rod attached to it by a conductor becomes an anode.

With regard to the lead plate type of accumulators (storage batteries), the + and — poles are easily distinguishable. Charged positive plates (peroxide of lead) (PbO_2) are a velvety chocolate brown color and hard like soapstone. It is usual to paint their lugs red.

Charged negative plates (sponge lead) (Pb) are of a pale slate or light grey color and can be cut into by the thumb nail. Their lugs are painted black.

It is well known that with magets unlike poles attract and like poles repel. The needle of a mariner's serviceable compass is a magnet and is acted upon by the magnetism of the earth. One end of the needle points to the earth's magnetic pole near the geographical north pole of the earth and is called the north pole or north end. Since like poles repel this would seem to be a misnomer and "north-seking" pole would seem more appropriate but owing to common usage the former term is accepted and is applied to all magnets. If we suspend a magnet by its center, its north pole will tend to swing so as to point northwards and the steel magnets on the market generaly have this pole marked by means of a prick punch or by a cold chizel, the other pole remaining unmarked.

Alfred W. Marshall, A.M.I.E.E., M.P., Mech. E., in his book, "Magnets and Magnetism Simply Explained," says (when referring to the name given the end of the magnet which will point north if free to do so): "Owing to this con-

fusion of meaning, various scientists have adopted or given other names to the poles of a magnet. The N pole as defined above is called Austral by the French, by mathematicians Positive (+), Lord Kelvin called it the True South, Faraday called it the Marked Pole, Sir G. Airey the Red (colored accordingly). The S pole is called Boreal by the French by mathematicians Negative (—). Lord Kelvin called it True North, Faraday called it the Unmarked Pole, Sir G. Airey the Blue (colored accordingly).

Now supposing we want to use a cell or a battery to produce an electro-magnet and want to make one certain end the North, N, +, Marked, or Positive pole of the magnet (the other end being of course the South, S, —, Unmarked, or Negative pole), we can easily manage that. Fig. 5 illustrates the direction in which the electric current must flow to produce a given polarity. This is right-hand winding but left-hand winding gives the same result, providing the current flows AROUND the bar in the same direction. The polarity is determined by the direction in which the current flows around the bar and is independent of the current travel from either end towards the other. Let one

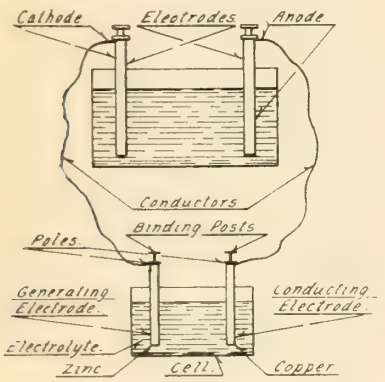

FIG. 8.

grasp the bar in his right hand and with the finger tips pointing in the direction of the travel of the current, the thumb, when extended along the bar, will point toward the magnet's north pole end. When looking at the end of the magnet, if the direction of the flow of the current is opposite to the travel of the hands of a clock or watch, then the end next the eye is the north pole end. Fig. 6 shows the north (+) and south ((—) ends of the magnet, the arrow heads indicating the direction of flow of current around them. Fig. 7 indicates the current flow and resultant polarity as applied to the field magnets of an overtype dynamo. From this fig. one can see how the principle applies to ordinary horse-shoe electro-magnets. The circles with arrows inside indicate the positions the needle of a mariner's compass would assume with the compass placed as indicated by the circles. When making small electro-magnets, if one finds that the polarity is wrong, all he has to do is reverse its connections to the cell or battery. Opposite connections gives opposite polarity. In the ordinary dry cell the central binding post belongs to the + pole of the cell and corresponds to the long thin mark given in the symbols.

Occasionally one is working away from where his source of (electric) current is and cannot see which pole or terminal either wire (conductor) is coming from or attached to, but if he has the right two conductors the polarity can be easily ascertained by the use of "pole-finding" paper, or, if this is not available, then by one of the following methods.

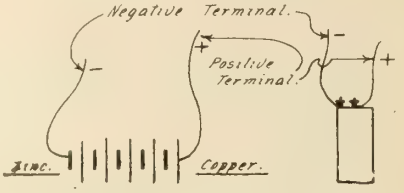

FIG. 9. FIG. 10

1. Use a few crystals of iodide of potassium dissolved in water. Insert the terminals. The liquid will take a stain, generally brown, at the positive terminal (the anode). Adding a paste of starch is supposed to cause a blue or violet color to the spot that occurs but I find the brown tinge quite persistent. As this preparation is liquid, or if thickened enough with starch, a paste, a dish is required for it while in use.

2. Blotting paper moistened in a solution of iodide of potassium in water will give a brown spot at the positive terminal. In this method the starch paste may be mixed in the above solution before dipping the paper but I do not think it any advantage to add the starch.

3. Place the wire ends into a solution of a tablespoonful of common salt in a pint of hard water. The one that sends up bubbles (or that sends up the most bubbles if both send them) is the negative pole.

4. Wet a piece of blue print paper and touch the two terminals to it. The negative terminal will bleach the paper white.

I have used each of the above successfully and with as low as four vols. I consider them sensitive in the order in which I have placed them here, the more sensitive ones mentioned first. The stronger the solutions of iodide or of salt the more sensitive I find them. The distance apart at which the terminals are held in the solution or on the paper also affects the length of time required to produce results. The blue print paper method may also be used on 110 volt circuits but on these and higher voltages the operator should guard against receiving a shock himself as the result of touching a bare terminal or handling the terminals without a proper amount of insulation to protect him.

The following methods are less sensitive than those already given unless in the case of a strong acid being used in this next one. They are arranged in the order in which I have found them sensitive.

5. To determine which is the positive and which the negative wire polish the wire terminals and insert them in an acid fluid. The positive end will tarnish quickly; the negative will remain bright.

6. Split or slice a potato and push both terminals into the fresh cut surface, the terminal around which the potato changes color (usually to a greenish shade) is the negative.

7. Place the wires a short distance apart in water, the wire from which the most bubbles rise is the negative.

I have referred to the fluid in a battery as being called the electrolyte. In chemistry, any substance whose solution will conduct an electric current is called an eletroclyte. Prominent among these are solutions of nitri acid, of hydrochloric acid, and of sulphuric acid. Solutions of the bases, potassium hydroxide, sodium hydroxide, barium hydroxide, and solutions of the following salts—potassium chloride, sodium chloride (common salt), ammonium chloride (sal ammoniæ), potassium nitrate (saltpetre) and potassium acetate. Some of these are seldom or never used in the sense in which an electrician employs what he commonly understands as "the electrolyte," and like the anode and cathode problem there is a chance for possible confusion if speaker's viewpoint is ignored or is obscure.

I have frequently seen in query columns in periodicals, questions identical with this. "If I cut a steel magnet in two, will I have two magnets, the one a north pole magnet and the other a south pole magnet?" The enquirer's idea seems to have been that the original magnet is all north pole from one end to the centre and all south pole from the other end to the centre, and that by cutting it in two he might isolate each pole and have single pole magnets. For use in some classes of "invention," this would come in very handy if it could be accomplished. In reality, when the magnet was cut in two, one would find that he had two magnets, each shorter than the original and each with north and south poles. One might as well expect to cut a string in two and each piece have only one end, as to expect to cut a magnet in two and each piece have only one pole. With equal magnetic density a short magnet (within certain limits) will support as much weight on an armature in contact with its pole as a longer magnet will support, but if used for drawing the armature to itself through a given air gap the long magnet will pull the same armature across a wider air gap than a short magnet will. If it is required that alternate poles of permanent bar magnets be presented, the method is to use two magnets placed with their north pole ends pointing in opposite directions. With electro-magnets reversing the flow of current reverses the polarity. As for the practicality of cutting steel magnets in two it must be remembered that hammering, jarring or other rough usage of steel magnets tends to weaken them and so should be avoided. Neither should poles be forced against one another.

The Canadian SKF Company, Ltd., have recently issued No. 5 of their Engineering Date Sheets. This particular sheet covers the application of ball bearing to fans of various types.

Boiler pressure minus cylinder pressure—What's the answer?

160 lbs. on the boiler gauge—145 lbs. on the indicator card—or 100° Super-heat at the boiler and only 20° at the prime mover? Conditions like this usually mean insulation that has gone bad from age or abuse.

But there's one sure way of constantly maintaining pressure and heat all through your plant—and that is with Johns-Manville Asbesto-Sponge Felted Insulation.

This insulation will retain its original thermal efficiency because, unlike others of felt, it is constructed of many resilient layers made of fibrous asbestos and sponge. It is not easily damaged by handling in shipping or after installation; it is adaptable to all steam conditions and this is in addition to the fact that thermally it is the most efficient commercial steam-pipe insulation known.

Ask any of our branches for detailed information about the way Asbesto-Sponge will keep your steam the closest to boiler pressure.

Williams' "Vulcan" Drop-Forged Chain Pipe Vises

ARE attachable anywhere—to bench, post, or other convenient support. They are compact in design — being smaller and lighter than clumsy, heavy cast tools. They are unbreakable—being made entirely of wrought steel. They are positive in their grip, readily adjusted, rapid and powerful in action.

When looking for a superior Pipe Vise, remember that Williams' Chain Pipe Tools have been *Standard* for nearly half a century and have behind them Williams' unconditional guarantee of service. Vises in 3 sizes—for ⅛ to 8-inch pipe.

May we send you a copy of our new catalog?

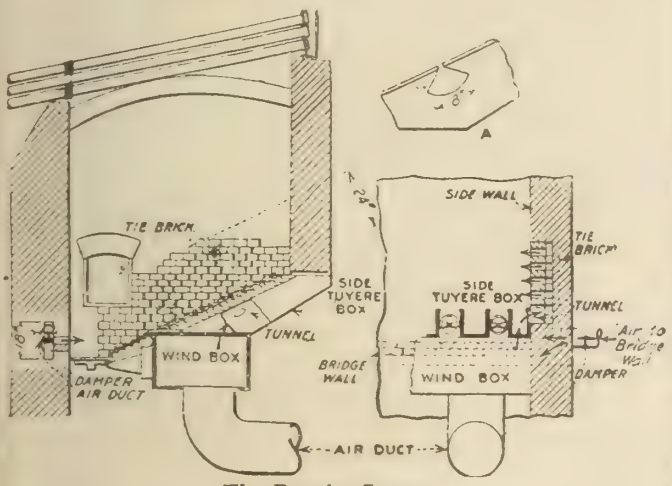
Add Power to Your Furnace—

by eliminating the fuel-waste resulting from the "freezing" of clinkers to the side walls. The Bernitz Method of constructing side walls with interior air passages through which cooling air currents are passed to keep the bricks below the fusing point will

Positively Prevent the Accumulation of Clinker Mass.



The Bernitz System as applied in a Taylor Stoker Installation

The Bernitz Method

1. Saves coal by insuring more perfect combustion of the fuel used.
2. Increases boiler efficiency by shortening time spent in cleaning walls.
3. Increases efficiency by burning coal which formerly clinkered.
4. By shortening time spent in cleaning walls reduces influx of air through doors.
5. Saves B.t.u.'s usually lost by radiation through side walls.
6. Permits increased forcing of fires by eliminating danger of clinker "freezing."
7. Makes it possible to remove such clinkers as are formed without dumping fire.
8. By reducing manual labor in boiler room keeps laborers more contented.
9. By keeping fires clean insures greater uniformity in heat applied.
10. Is equally applicable to old or new constructions.

The Bernitz Method is licensed, not sold. It has received full patent protection in Canada and in foreign countries and licenses under these patents are being granted on the basis of the H.P. rating of the boilers under which the Method is to be installed.

ENGINEERING EQUIPMENT

DEPARTMENT OF LABOUR

Ontario Government

Minister:
Hon. W. R. Rollo.

Deputy Minister:
W. A. Riddell, Ph.D.

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a STATIONARY steam plant of 50 B.H.P. or over, in the Province of Ontario, must hold a Stationary Engineer's certificate from the Board of Stationary & Hoisting Engineers. Anyone operating such a plant without a certificate is liable to the penalties set forth in the Act respecting Stationary and Hoisting Engineers.

After January 1st, 1920, the Certificate issued by the Board will be of four grades viz First Second, Third and Fourth. Application forms for graded certificates will be mailed upon request after the above-mentioned date. The certificates now issued by the Board will be graded into Third and Second-Class upon renewal, same being classified from the information contained in the renewal application which will be sent to each certificate holder.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse-power, and used for hoisting or conveying persons or for operating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a certificate is liable to the penalties set forth in the Act respecting Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1st, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request. The B.H.P. and other information contained in these forms is to be used for statistical purposes. A Registration Certificate will be issued to each applicant. All applications, or requests for same, should be mailed to the Chairman.

W. C. MCGHIE, CHAIRMAN OF BOARD

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., c. 61.

Before any work of repair or alteration is commenced in any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, Parliament Buildings, Toronto.

D. M. MEDCALF, CHIEF INSPECTOR OF STEAM BOILERS

WANTED

First-class machinery draftsman, by large Canadian in city near Toronto. In making application give details of experience, age and salary desired, etc. Apply Box 205, Power House.

WANTED.—Second-hand crude oil stationary engine, about 50 H.P., or two engines that will give that power.

The Miramichi Quarry Co., Ltd.
Quarryville, N.B.

WANTED

Representatives to handle special line of British made "Elastic Steam Jointing Cement" (for all joints) and Iron Cement for casting, etc. Exclusive territory offered parties conversant with trade. Replies treated confidential. Apply Box 151, Power House.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 TO 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

NEW PUBLICATION

The Franklin Manufacturing Company, Franklin, Pa., have recently issued a publication on heat insulation. This publication is entirely unlike the ordinary commercial catalogue and has been brought out with the idea of assisting the designing and operating engineer in the choosing of heat insulation of various types. To this end, in addition to the descriptive matter pertaining to the various types of insulation manufactured by the Franklin Manufacturing Company, a major portion of the book is devoted to heat transmission and loss problems and formulae, together with tables and charts.

A YARD OF INSTALLATIONS

The average buyer of power plant equipment, especially if the purchase cost runs into three or four figures likes to visit some neighboring installation to see the equipment in use.

The next best thing to a visit is a pictorial reproduction of the installations.

"A Yard of Installations" aptly describes the latest folder put out by the American Steam Conveyor Corporation, Chicago, with this thought in mind.

This folder shows in an attractive panel, views of installations of the American steam ash conveyor. The folder itself is about a yard in length, as the title indicates, and some nineteen or twenty installations are pictured.

This folder is being extensively distributed among power plant executives and is one of a series of pieces being issued.

The Canadian Ice Machine Co. have recently changed their Toronto address from 82 Chestnut Street to Villiers and Munitions Streets.

WANTED

Power House Engineer, holding second-class Provincial certificate as assistant to chief engineer, for large industrial plant near Montreal, must be experienced in the operation of D.C. generating sets, transformers, air compressors and hydraulic pumps. Permanent position for the right man. Applicants speaking English and French given preference. State experience, qualifications, age and salary expected. Box 206, Power House.

THE LONG Patent Steam Trap

Has Only One Moveable Part

The Long Patent Steam Trap is advanced in construction. Has positive advantages over all other traps, and is protected by patent rights.
The valve is actuated by the expanding and contracting of a tube, a motion that is positive and of sufficient force to close the valve against a pressure of 200 pounds. The movement is due to the expansion and contraction of different metals.
Works against 1 and 200 pounds of pressure—no possibility of freezing. Has two outlets so it can be installed in any position. Applied to drain steam lines, mains, Jacket kettles and separators and can be adopted in drying room systems.

FULL DETAILS UPON REQUEST. YOU'LL SAVE MONEY.

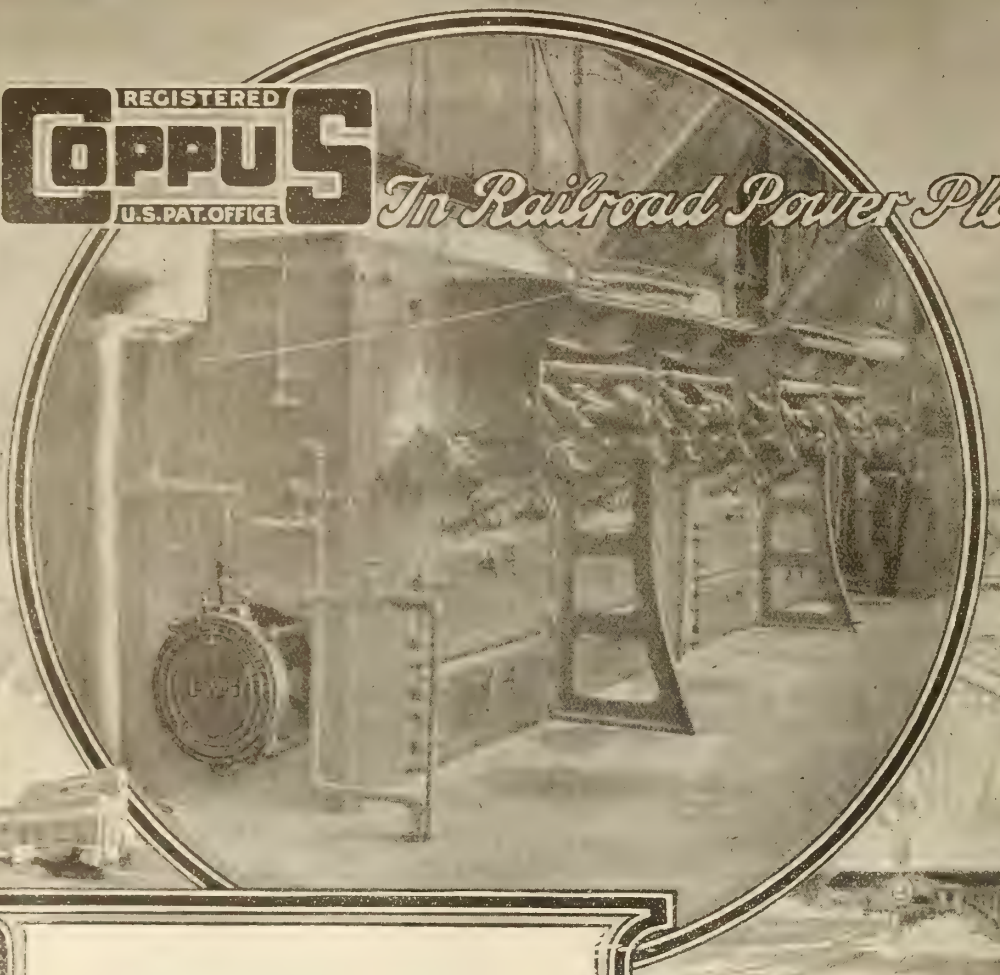
REGISTERED COPPUS U.S. PAT. OFFICE

In Railroad Power Plants



Railroads are sticklers for efficiency. Equipment approved by them must produce results — save money — earn dividends. The fact that the Central Railroad of New Jersey operates twenty-six COPPUS Turbo Blowers in their great shops at Jersey City —proves that these blowers **pay.**

Every one of this big battery of blowers—one of which is shown above—has cut coal costs—reduced labor charges—and saved dollars. In this power plant—as in thousands of others—COPPUS Blowers keep up steady steam pressure—prevent clinkering—meet peek loads quickly—and burn cheap fuel. COPPUS Blowers **pay a profit** to the Central Railroad of New Jersey. **They can do as much for you.** Why not put them on the job? Catalog H-22 will show you how

SAFETY FIRST

The NONPAREIL Shaking and Dumping Grates

Established 1900

Save 10% In Fuel Expense

OUR GUARANTEE SHOULD DECIDE YOU TO GIVE THEM A TRIAL. Nonpareil Shaking and Dumping Grates are put under any kind of a boiler for a test period of 30 days. If they fail to save 10% in fuel bills and do not prove entirely satisfactory they may be removed and shipped back to us—we will pay the freight.

There's no better way to meet fuel scarcity and high prices than by installing the Nonpareil Shaking and Dumping Grates. They will save 10% of your present fuel expense by giving complete combustion for every pound of coal used. You can use low-grade fuel, too, and secure maximum results. These are statements born of facts which we are prepared to prove.

Simple enough for a Girl to operate

Grate bars and repairs to all shaking grates and boilers of all sizes. Fire brick work, building in boilers, and general repairs.

ASSURES EFFICIENCY--SAVES MONEY

THE McDONOUGH DAMPER REGULATOR

This Damper Regulator saves $300 per boiler annually in many plants. It will on ½-lb. variation regulate Dampers, Stoker Engines, Stoker Motors, Forced Draft Engines, Gas Supply to Boilers. We put in the Quality before we put on the name.

We install this Damper Regulator in your plant for 30 days' trial, free of cost to you.

THE FEED WATER REGULATOR

We know positively that this Feed Water Regulator does what other Regulators try to do—maintains a flow of water to your boilers at the exact rate it is being evaporated into steam, that means boilers give drier and more steam for less money than is possible with other Regulators.

Two Good Reasons WHY:

Pittsburgh, Pa., Sept. 19, 1918.

We have your letter of August 9th and wish to advise you that we have your Automatic Regulator installed in our power plant, in this city.

We have been keeping record of the coal used in anticipation of this installation, and find that we have an actual saving in coal alone of twenty-five (25) per cent. for the past three months, with considerable of an increase in our factory production.

JAS. H. MATHEWS & CO., INC.,
(Sgd.) Jas. H Mathews, Pres.

Toronto, November 17th, 1918.

We have had the McDonough Automatic Damper Regulator System and Feed Water Regulators System in use for more than six years in our Old and New Plants and we are pleased to state that these two controlling systems have been satisfactory and we find same a great saving equipment giving us steady water level in our boilers and a steady head of steam as well. We will be glad to recommend these controlling systems to prospective purchasers of steam plants.

"We Install a Jenkins Bros'. Valve With a Feeling of Confidence"

THIS is the actual statement of a prominent engineer, just after he had installed a genuine Jenkins Bros.' Valve in a troublesome line.

"That extra metal that Jenkins puts in his valves is just where it's most needed and I've never known a 'Jenkins' to break down even on a line where the pressure and strain is greatest."

Over fifty years of valve making is behind genuine Jenkins Bros.' Valves. They are the result of a thorough understanding of valve requirements and valve uses.

Jenkins Bros.' Valves are of all types and sizes for all uses, made of brass, iron and cast steel. They are distinguished from their imitations by the "Diamond Mark" cast on the body.
Look for it—demand it.

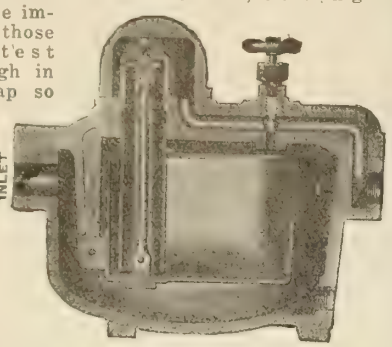
KIELEY

IMPROVED HIGH AND LOW PRESSURE

STEAM TRAP

For General Service

No power plant should be without a dependable steam trap. It is the great economizer of fuel and promoter of power plant efficiency. The KIELEY Improved Trap is the latest development in the art of steam trap construction, and is suitable for all service, either high or low pressure. The important parts and those subjected to greatest wear are placed high in the top of the trap so that by removing two nuts and the small cap all parts are easily accessible and removed for repairs — no breaking of connections necessary, neither do you have to remove the cover. Seats and discs are of best metal, absolutely non-corrosive; for exceptionally severe service seats and discs are constructed of nickel or monel metal, and the bodies of cast iron. Kieley traps never leak when in service—our water seal assures you this.



Leaky, unreliable steam traps are expensive. Adopt the KIELEY and be certain of efficient, economical service.

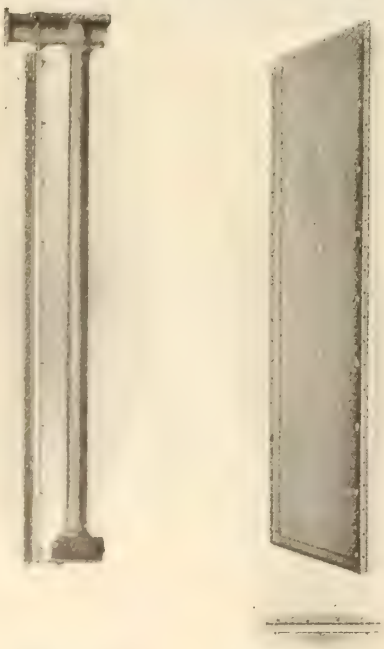
Sectional Covers

Article No. 7



Sectional covers consisting of two steel plates with about 2 inches of magnesia or asbestos insulating material between them are now used in the majority of cases for enclosing one or both sides of the Economizer in preference to the older method of bricking it in.

The edges of the outside plates are fitted with stiffening angles so punched or drilled that when the sections of covering are in place, bolts can be slipped through and the edges drawn snugly together, making the covering practically air-tight, as well as heat-proof.

This covering has a big advantage in that it may be easily taken down and replaced if it should be desirable to gain access to the Economizer for inspection or cleaning.

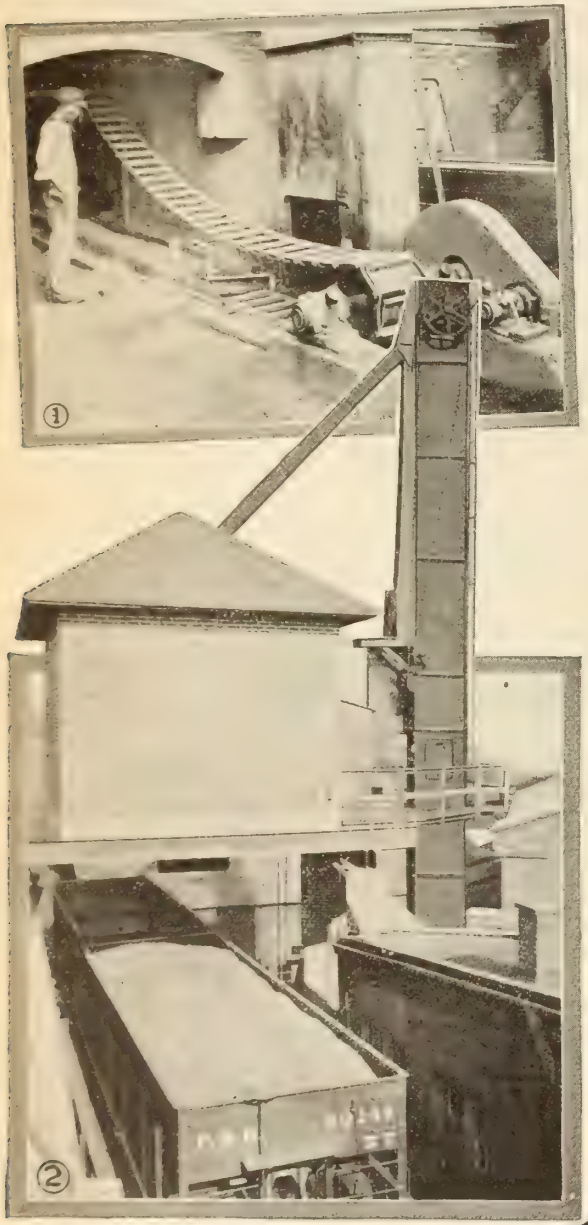
LINK-BELT
CONVEYORS FOR ASHES



LET us show you how easily Link-Belt Machinery can solve that bothersome problem of disposing of your ashes.

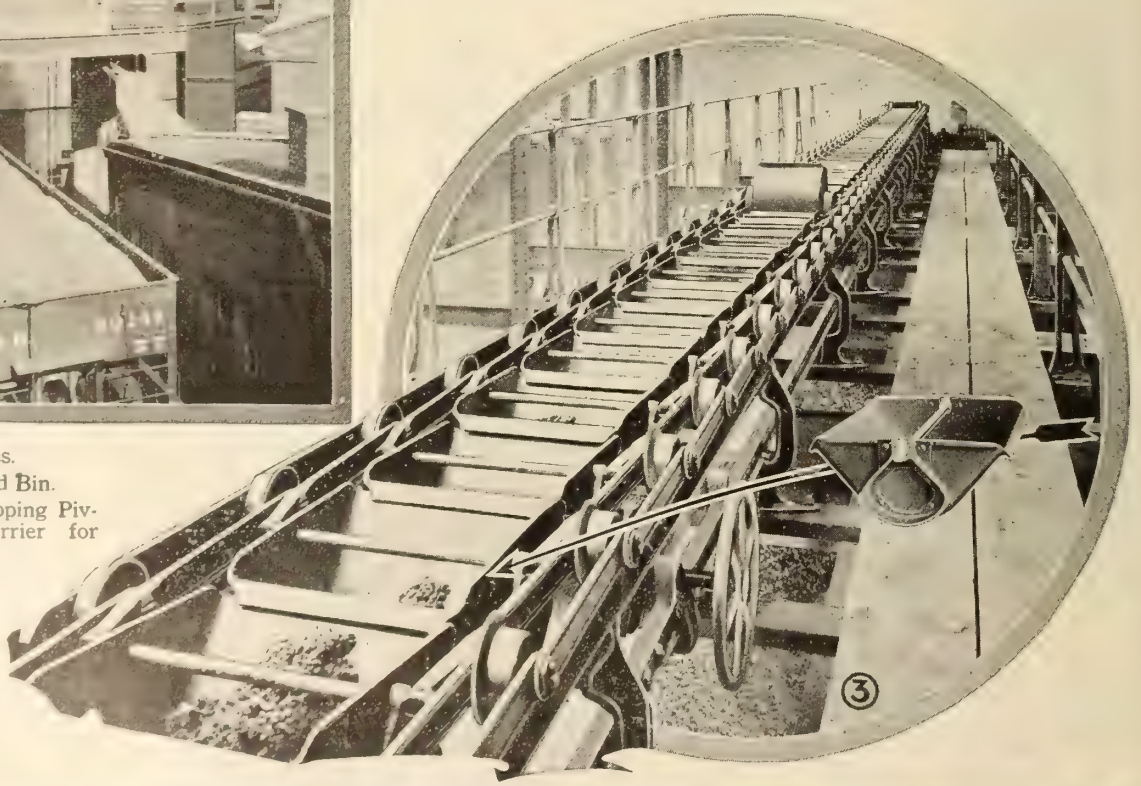
Link-Belt machinery starts with handling and preparing coal right at the coal mine, and the same efficient methods employed by us for the handling and preparation of coal at the mine is also employed for handling coal at the power house and removing the ashes.

Ask us to send one of our experienced engineers to look over your present handling methods and let us develop a standard Link-Belt plan to do this work for you in the most effective and economical manner. We also design and build labor-saving conveyors for handling miscellaneous materials of all kinds; coal handling machinery, locomotive cranes, portable wagon loaders, electric hoists. Catalogs on request.

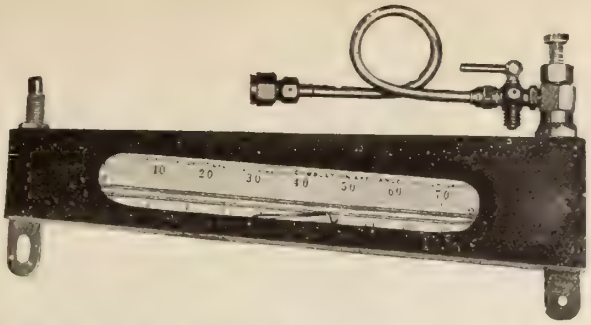
CANADIAN LINK-BELT COMPANY LIMITED

WELLINGTON AND PETER STREETS, TORONTO

1. Conveyor for Ashes.
2. Ashes Elevator and Bin.
3. The Peck Overlapping Pivoted Bucket Carrier for coal and ashes.



The Peck Carrier is the recognized standard machine for handling both coal and ashes in the modern Boiler House.



The Hays Differential Draft Gauge indicates the draft over the fire or the drop in draft through the boiler.

GUESSING IS A LUXURY—

Hays Improved Gas Analyzer

For testing boiler furnace gases, producer gases, casing head gas, exhaust from internal combustion engines, gases from sulphur burners, nitric acid gases, chlorine gas, etc., etc.

the greatest extravagance an engineer can indulge in.

Without exaggeration, 25% of all the fuel used under steam boilers on the North American continent is wasted by preventable heat losses in the boiler furnaces alone.

Look over the list of the possible and common causes of heat losses in boiler furnaces. In how many cases have you no check on losses from these causes in your boiler plant—in particular, no knowledge of the amount which is actually preventable? **In how many cases are you guessing that everything is all right?**

You can't even locate losses by guesswork. You can't eliminate them when you don't know where they exist. There is only one sure way—locate and measure the losses with

HAYS COMBUSTION APPARATUS

Sources of serious fuel losses which are largely preventable:

Excess or insufficient supply of air.

Leaky boiler setting.

Leaky baffles.

Holes in fire.

Unburned coal in ash.

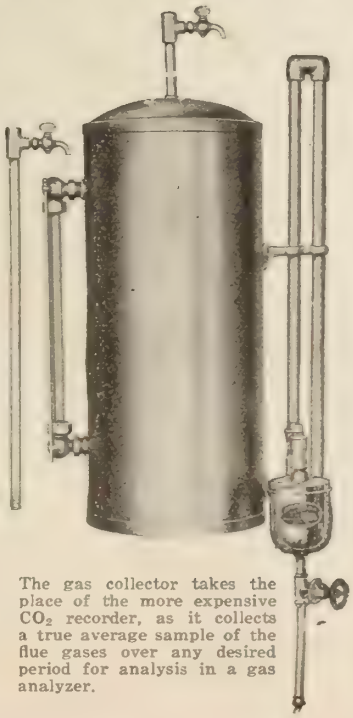
Fire too thin or too thick.

Firing periods improperly timed.

Fire cleaning periods improperly timed.

Draft too weak or too strong.

With measuring instrument you can isolate and measure the losses due to these causes in your furnace—you can only guess at them without. Can you afford to be without the instruments?



The gas collector takes the place of the more expensive CO_2 recorder, as it collects a true average sample of the flue gases over any desired period for analysis in a gas analyzer.

Then you have a basis to work from and a standard to work towards.

Ask for our book, **"How to Build Up Furnace Efficiency."** It is a treatise on boiler losses and their prevention—shows where fuel is wasted, how to stop the waste and keep it stopped.

We manufacture:

Draft Gauges—Indicating and Recording.

Automatic CO_2 Recorders.

Automatic Flue Gas Collectors.

Engineers' Gas Analyzer—a modified "Orsat."

Practical, sturdy instruments meant for continuous use in the boiler room.

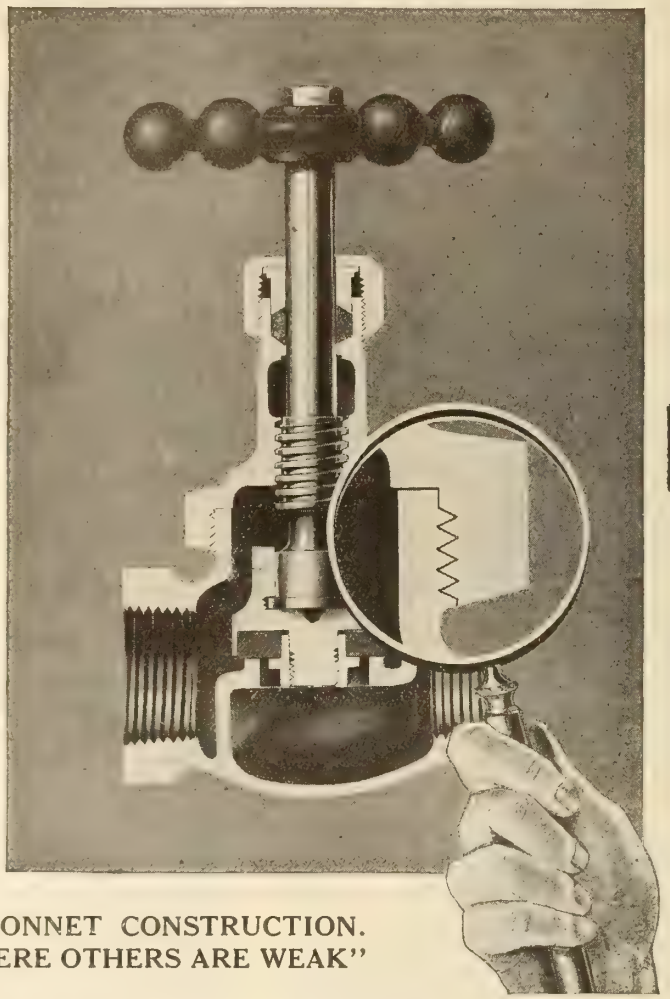
COMPODISK

PENBERTHY



PENBERTHY

"OUTSIDE BONNET CONSTRUCTION.
STRONG WHERE OTHERS ARE WEAK"

VALVES OF QUALITY

A STEP FORWARD!

DO YOU KNOW?

That the Penberthy VALVE was the FIRST VALVE made in Canada "with the outside bonnet construction."

***It is the first* radical and important improvement made in valve construction for generations.**

ALL Penberthy Valves are designed with outside threads on the bonnet end of the valves. When tightening down bonnet to place, this construction prevents spreading or enlarging bonnet end of body, causing a loose fitting and unsafe valve. The threads, being on the outside of the body, are immune from the corrosive action of the steam and water, preventing the body and bonnet from freezing together, eliminating all strains and making an extraordinary strong valve at the vital point where others are weak.

Manufactured by

PENBERTHY INJECTOR CO., LIMITED WINDSOR, ONT.

FOR BAND SAW MACHINES

WESTERN PINE MFG. CO.
—Manufacturers—
Lumber, Sash and Doors
Spokane, Wash.

Magnolia Metal Co., May 28, 1919.

Gentlemen:—

As nearly as I can recall, I began using MAGNOLIA METAL twenty-seven years ago. I have, from time to time, used other babbitts, but have always come back to using MAGNOLIA.

The most important machines around this plant are babbitted with MAGNOLIA METAL. The MAGNOLIA lined bearings on one American Band Resaw, doing extra heavy work, show no particular wear after seven years of continuous service.

I have always given particular attention to the melting and pouring of babbitt metal, preparing the boxes to be babbitted, cleaning well and heating the box. I never mix the scrap babbitt from the old box with the new metal. Always heat the metal only enough that it browns a white pine stick easily and pour while hot.

Yours very truly,
WESTERN PINE MFG. CO.

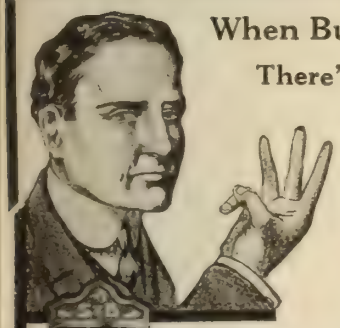
The J. C. Wilson Mfg., Co., Limited

BELLEVILLE, ONTARIO

Mechanical Engineers, Pattern Makers, Founders and Machinists. We build complete Hydraulic Turbine Equipment, Flumes, Head Gates, Racks, Waste Gates and Winches. Water Wheel Governors, Gearing, Pulleys and Shafting.

MAKERS OF THE "LITTLE GIANT" TURBINE

Put Your Water Wheel Proposition Up To Us



When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.

Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

Get a copy of Catalog P.H. 200 to-day.

Canadian Agents:

Milton and Prentiss,

Power Plant thermometers for all temperatures not exceeding 1000° F.

Also—"Columbia" Recording Gauges and Thermometers, Gauges, Gauge Testers, Tachometers, Steam Calorimeters, Counters, etc.

"SAFETY FIRST"

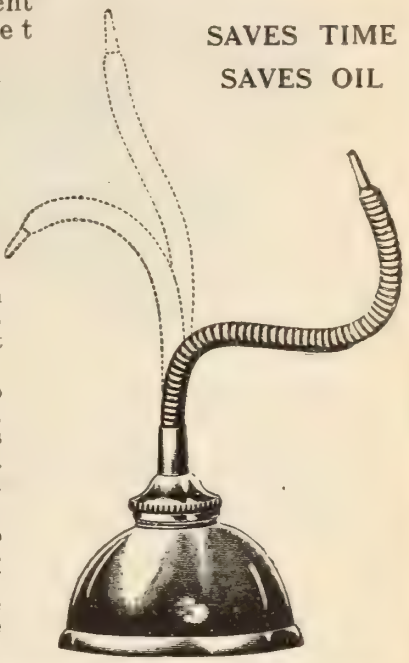
Bend the Spout

to suit the position

Every requirement satisfactorily met with

ALL-WAY OILERS

SAVES TIME
SAVES OIL



Note the flexible spout. It enables you to oil all places—many places that previously could only be reached with force pump cans with specially bent spouts.

Indispensable to those who know. Will last as long as six ordinary oil cans. Saves 50% of oil bills.

Ask your dealer to show you the complete ALL-WAY line of oilers. If he cannot do so, please write to us.

LUNKENHEIMER "RENEWO" VALVES

The "seat guard" with which the "Renewo" is provided aids in preserving the seating surfaces and keeping them clean. The seating surfaces are regrindable and all the parts, including the **seat ring** and **disc** are renewable. To further enhance their durability, both the **seat ring** and **disc** are made of Lunkenheimer "Valve-nickel"—a material having exceptional wear-resisting qualities.

The body, bonnet, stem, etc., are made of high-grade bronze composition formulated especially for the duty each part performs, making the **"Renewo"** the most practical, durable and economical valve to be had.

Globe, Angle, Cross, Straightway and Horizontal and Angle Check types for pressures up to 200 and 300 pounds.

Specify **Lunkenheimer "Renewo"** and insist on getting the genuine. Your local dealer can furnish them, if not, write us.

Write for Booklet No. 535---D.C.

The Jeffrey Carrier

Requires Little Lubrication

THIS desirable feature of the JEFFREY Pivoted Bucket Carrier is obtained by the use of large rollers and glass-hard bushings. The extra-sized rollers give increased leverage to the oiled bore with a corresponding decrease in both the speed of the rubbing surfaces and the horsepower pull.

The new **JEFFREY Roller** is a marked improvement over all others. It is so hard that it resists the action of high-grade machine tools. The bore is, of necessity, ground on a special grinding machine.

There are many other unique features embodied in the JEFFREY Carrier. Catalog No. 210 gives full details. Write TO-DAY for your copy.

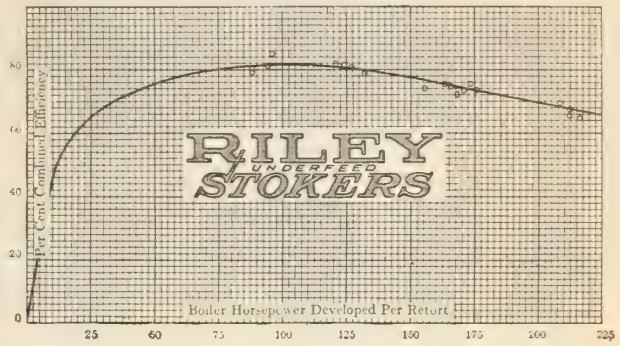
ARE YOU WASTING COAL?



If your boilers are operating at 65% efficiency, whereas you ought to be getting 75% or 80%, then you should investigate to-day the possibilities of RILEY UNDERFEED STOKERS.

The first year after installing Riley Stokers, the Haverhill Boxboard Company saved ten tons of coal a day, and reduced their operating force by thirty-six men—a total saving of $52,000.00.

Our catalog shows a cut of an evaporation curve. From it you can figure just what you can actually save in dollars and cents by increasing your efficiency.

Catalog HR 2 sent on request.

For information on Murphy Automatic Furnaces for small boilers, see Jan. 20 advertisement or send for Murphy Furnace Catalog HM 2.

POWER HOUSE

Twice a month—$2.00 per year.

Serves the power plant engineer—Steam, Electric Refrigeration, Hydraulic.

CANADIAN MACHINERY

Weekly—$3.00 per year.

Covers the metal working field—serving shop executives, purchasing agents and owners. First-class mechanical paper and market paper combined.

CANADIAN FOUNDRYMAN

Monthly—$1.00 per year.

A paper for the foundry owner, superintendent and foreman. Claimed by its readers to be unexcelled.

MARINE ENGINEERING

Monthly—$2.00 per year.

Interprets marine engineering in its broad sense, serving the shipbuilders, navigation companies and their officers. (The editor holds an extra first-class B.O.T. certificate).

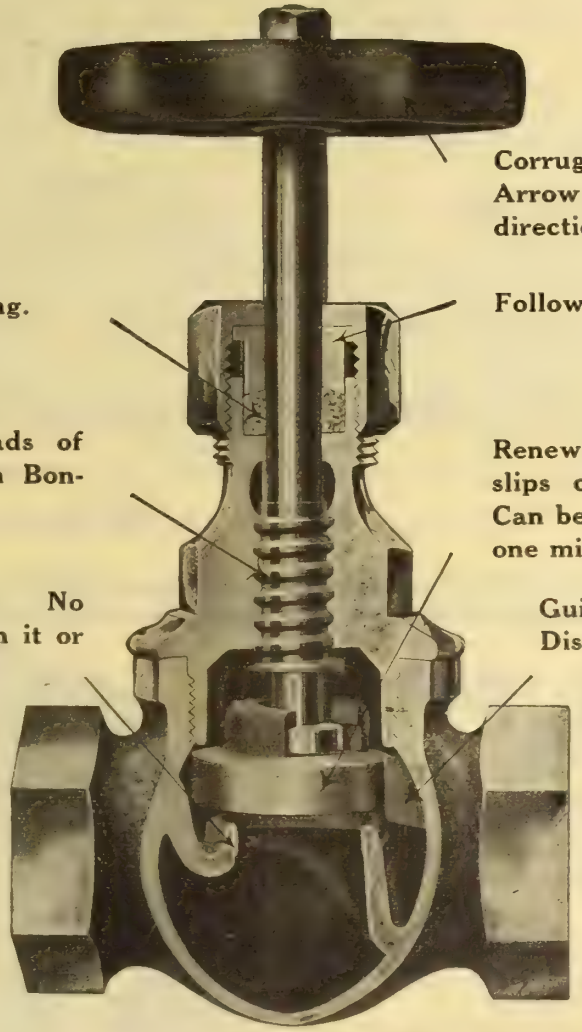
Fairbanks Renewable Disc Valves



Corrugated Iron Wheel, Arrow cast on wheel shows direction valve opens.

Palmetto Twist Packing.

Follower in Stuffing Box.

At least Four Threads of Spindle engaged with Bonnet at all times.

Renewable Bakelite Disc slips over end of spindle. Can be replaced in less than one minute.

Raised Round Seat. No sediment can lodge on it or injure disc.

Guide cast on Body holds Disc centrally over seat.

Globe or Angle

Screwed or Flanged

The disc of the Fairbanks Renewable Disc Valve can be renewed in less than a minute without removing the valve from the line, a wrench being the only tool necessary.

Everything in Mechanical Goods.

METLSKIN

prevents boiler-scale

by a process which is mechanical, rather than chemical. It forms a minute, grayish-white coating which keeps scale-forming solids from adhering to the boiler metal, and, therefore, these solids must settle to the mud-drum, whence they may be discharged through the blow-off.

METLSKIN is distinctly **not a compound,** nor does it contain any soda ash, graphite, kerosene, or tannin. It works by expansion, without harm to anything save boiler-scale itself.

The Two Months' Test

may be adopted by any reputable concern troubled with scale. METLSKIN will remove the old incrustation safely but gradually, will ultimately produce clean boilers and then **keep them clean.**

Send a post card for terms and full details.

NOPORO

air-proofs boiler-settings

by maintaining an air-tight seal on the exterior surfaces of the brickwork. After a thorough application, by means of a trowel, NOPORO forms a covering that looks and feels very much like coarse, black grain leather. The surface may be whitewashed after an interval of 6 to 8 days, while the material below the surface retains its plasticity. It will not peel, check, or disintegrate, and will **stay put** for years. No further attention need be given it.

An Immediate Saving

may be effected, since NOPORO promptly prevents the entrance of cold-air into the furnace chamber. That means better fuel-combustion, less firing, less coal. NOPORO pays for itself from the first.

Mail a card for prices and descriptive folder.

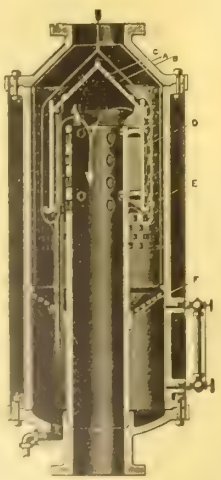
III IMPORTANT THINGS

TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

Tuxeda
SWING JOINTS

Provide one of the easiest ways to save coal

Every pound of steam that escapes through a leaky connection represents a certain amount of coal wasted. Do you know that an average leak will waste 3,400 pounds of steam a month? Investigate your flexible steam connections at once and then investigate the Tuxeda Swing Joint.

The Power You Pay For

YOU pay for power according to the coal you burn, but you *get* what your belts deliver. A fraction of 1% saved in power transmitted soon pays the cost difference between a poor belt and a good one. One breakdown may wipe out ten times the cost of any belt.

The right belt in the right place boosts profits.

Among Graton & Knight Leather Belts there are *right belts* for every drive, belts that will deliver maximum power year in and year out without a halt.

They do this because they are made from leather—tanned in our own tannery especially for belting purposes. This preserves and intensifies the strength, toughness and flexibility of the hide as worn on the back of an active, living steer.

Skilled workmen make this specially tanned leather into a Standardized Series Leather Belts—belts for every drive standardized in manufacture and in application.

Our booklet, "Standardized Leather Belting," explains how to find the *right belt*. A copy will be sent you upon request.

Engineering Note

Our Engineering Department is at your service to answer any questions you may have about belting and its use. There is no obligation involved.

Here is a 48" 3-ply Heart Brand belt in the mill of Joseph Bancroft & Sons Co., Reading, Pa. More than 3½ years of steady service. Transmitting 300 horsepower at a cost to date of less than one cent per week and good for many years more.

Like Putting a New Blade in Your Safety Razor

When your safety razor blade is worn out you replace it with a new one—you don't throw the razor away.

The same principle applies to the Pratt & Cady *Renewable* Disc Globe Valve. When the disc becomes worn from hard use you put a new one in its place—you don't throw away the entire valve.

In other words, you simply pay 25c for a new disc instead of $2.50 for an entire new valve in the 1″ size. Then your Pratt & Cady "Renewable" is as good as new.

Old style razors and old style valves have to be discarded entirely when worn past use. Both are a dead loss.

Factories using Pratt & Cady Renewable Disc Valves cut down valve-costs to a minimum.

The operation of replacing a worn disc is a quick one, requiring only a few minutes. And the change can be made without removing valve from the pipe line.

An economy of this kind is worth thinking about. Many plants are saving big sums annually by putting in a "Pratt & Cady" every time an old-style valve goes bad.

Our Valve Book contains some facts that will interest you. We'll send you a copy on request. No obligation.

RENEWABLE DISC GLOBE VALVES

Advertise for Good-Will

"The last twenty years have witnessed a great development of advertising as a selling force," George Frank Lord, advertising manager of the E. I. du Pont de Nemours & Co., told the Pittsburgh Advertising Club.

"I venture to predict that in the next five years advertising will be recognized chiefly as a great buying force. Instead of using advertising to sell merchandise we will use it to buy customers. For the purchase of good-will it will be classified, even by accountants, not as current expense, but as a long-time investment; a sort of bond that yields dependable interest annually and amortizes itself in ten years, but keeps on returning interest indefinitely.

"If advertisers and advertising men will keep their minds fixed on this idea of buying good-will, or buying satisfied customers, instead of selling merchandise, many of the most difficult problems of advertising will disappear. Appropriations will not be based on last year's earnings, the current year's estimate, the sales department's gross margin, or the tentative impulses of the board of directors, but on clear analyses of the amount and kind of good-will needed for the ideal future of the business, the time required or available to develop it, the total amount it will be worth, and how the expenditure of that total will be made in various years.

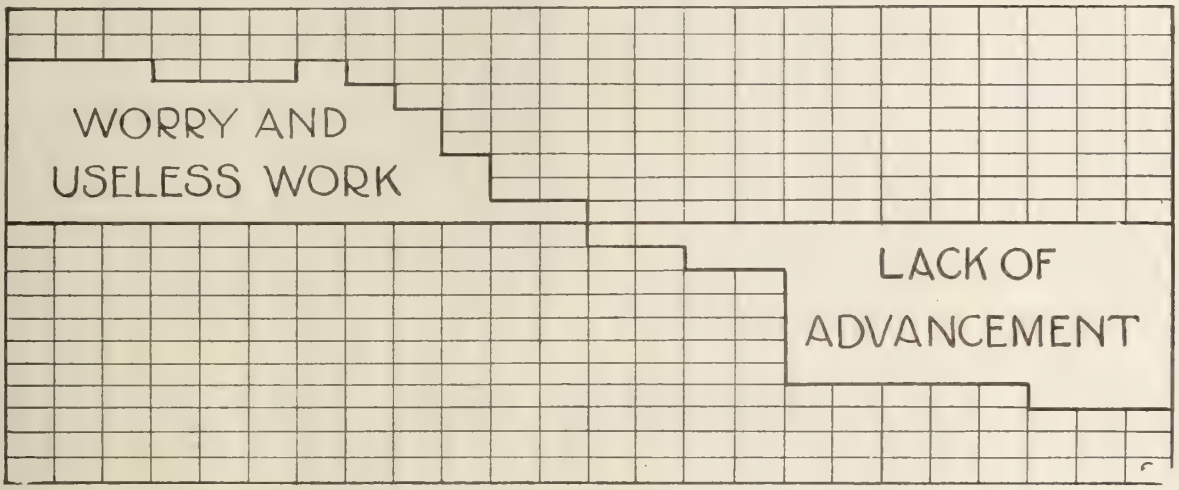
"The advertising policy will not be shifted by the weather, the crops, temporary trading conditions or changes in organization. The business itself will have a definite, enduring policy, and the advertising will express it.

"There will be no lying copy, nor merchandise that is made only to sell, and not to use; because such things do not buy customers and are destructive of good-will, the great asset the advertiser is seeking.

"Whether an advertiser formally adopts the policy of buying good-will or not, the good-will value of his advertising is all he really gets for his money. The advertising that buys satisfied customers adds to his good-will, and that which creates dissatisfied purchasers subtracts from his good-will.

"Success is merely the result of having more plus than minus in the good-will account. Since the whole history of advertising proves this is true, why should we not recognize this truth and consciously get in line with it?"

Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

CANADIANS MUST BE SQUARE

IN the course of an article in January issue of MACLEAN'S MAGAZINE (now on sale), Mr. Lloyd Harris, who was head of the Trade Mission to Great Britain, makes the important statement that "Canada must develop a high standard of commercial morality—she hasn't that standard now." This is a vitally important article, pointing out the tremendous opportunity for profitable trade in Europe that is open to Canada, but at the same time issuing a grave warning as to what we must do, and must not do, if we are to grasp the golden chance.

Mr. Harris shows the opening for permanent trade connections that has come about as the result of war conditions and the "sentimental preference" that Canada now has in Europe—a preference created by the record of our soldiers. His message is one that every Canadian should read—business man or workingman, exporter or laborer.

Other features found in January MACLEAN'S are:

"Politics Under the Shadow"

Dominion politics are summed up by J. K. Munro in his usual pithy and unsparing style. He tells what is happening in Ottawa where the shadow of an impending farmer invasion hangs over everything.

"The Woman's Court"

Mrs. Arthur Murphy (Janey Canuck), the first woman magistrate to sit on a bench in Canada, tells of the operation of the first Woman's Court.

"The Birth of a Labor Party"

Up to the recent election in Ontario, Canada hadn't a real Labor party. As a result of the return of a solid group of Labor candidates, a new party may be said to have been born. J. L. Rutledge gives interesting sketches of the first Labor members.

"A Woman on the Warpath"

Mrs. Nellie McClung, who has figured on the public platform more prominently than any other Canadian woman, tells interestingly of her experiences, particularly with regard to the campaign in Manitoba against the Roblin Government.

Six Bright Stories by Well-Known Authors

The Thread of Flame—By Basil King.
His Majesty's Well-Beloved—By Baroness Orczy.
Spanish Doubloons—By Camilla Kenyon.
The Fall Triumphant—By C. L. M. Brown.
The Empty Chair—By Alice and Claude Askew.
Winning a Post in Fur Land—By Robert E. Pinkerton.

Keep in Touch with the World

The world is being remade in these trying times and the man or woman who would keep up with the march of events, can do no better than read the "Review of Reviews" department in January MACLEAN'S, in which the best articles and most interesting selected from the periodicals of the world are reprinted in condensed form. Look at the list of articles in this department in January MACLEAN'S:

Showing ease with which Plibrico is laid in place.

PLIBRICO

A High Grade Refractory for Furnace Linings

BETTER THAN FIRE BRICK

1. It's Jointless.
2. It's Plastic.
3. It's air and gas tight.
4. It will stand 3100° F.
5. It will save fuel.
6. It can be installed by inexperienced labor.
7. It will outlast fire brick.
8. It can be used in any boiler, furnace or oven.
9. It can be used wherever fire brick is used.
10. It can not be excelled for patching broken and burned out linings.

Any Engineer can see the economy and advantage over Fire Brick

Write for book on furnace building

Pushing Prosperity's Production

"Increased production, a world necessity," without which business will be helpless in the face of rising wages and increased cost of living, was discussed by eminent leaders of industry at the recent great advertising convention.

Mechanically, its solution depends on the boilers of the nation.

Backing up the boilers are the Twin King-Pins of Production, the:—

—**Coppus Turbo Blower,** which increases boiler capacity, reduces fuel costs through better combustion, makes available the mountains of low-grade fuels by giving a more perfect **air** supply.

—**Coppus Turbo Boiler Feed Pump,** which prevents shutdowns, lengthens life of equipment, and reduces operating costs by assuring a more perfect water supply.

With these two any plant can increase its power production and decrease its production costs. Toward the direct solution of your own problems in meeting rising costs we offer you the service of our engineering department.

Write for Catalogue H-23.

You can patch up holes in your Boiler Furnace Lining

in a Jiffy

with

PYRO-PUTTY

TRADE MARK REG U S PAT OFF

FIRE BRICK IN PUTTY FORM

The World's Best Furnace Lining Material

PYRO-PUTTY comes to you in a stiff, moist, pliable, "ready to use" condition. PYRO-PUTTY enables unskilled labor to make furnace lining repairs in less time and at less expense than would be possible with standard fire bricks. Simply clean out the breaks in the walls, pound in PYRO-PUTTY with a mallet, smooth it off with a trowel and you'll have a patch that will out-wear the rest of the furnace lining.

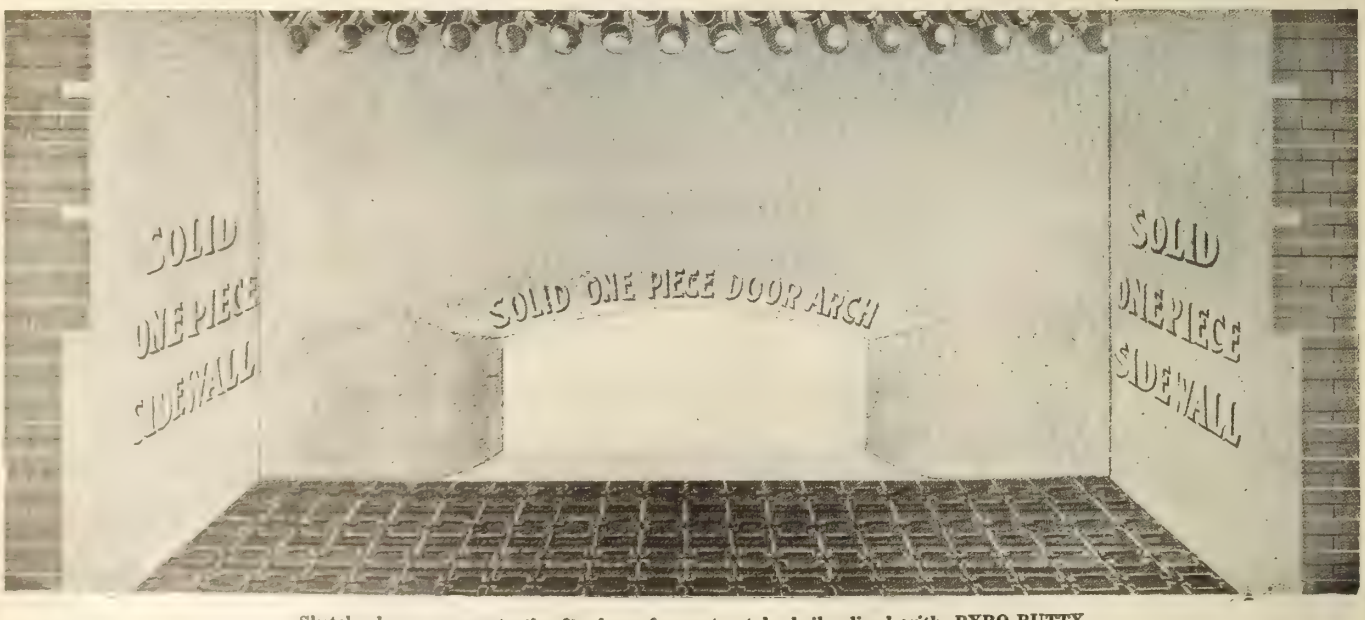
Pyro-Putty is far more durable than standard Fire Bricks for making New Furnace Linings

PYRO-PUTTY should be used, in preference to standard fire bricks, for making complete furnace linings because it is far more durable. And furnaces lined with PYRO-PUTTY are both efficient and economical because there are no joints to let the hot air out or the cold air in.

PYRO-PUTTY is put up in 700-lb. barrels, a barrel being equivalent to 100 standard fire brick. Sketch below represents the fire box of water tube boiler lined with PYRO-PUTTY. Compare it with your own fire box linings—then

ORDER A FEW BARRELS OF PYRO-PUTTY NOW!

"A few barrels of Pyro-Putty should be part of the emergency equipment of every steam power plant"



Sketch above represents the fire box of a water tube boiler lined with PYRO-PUTTY.

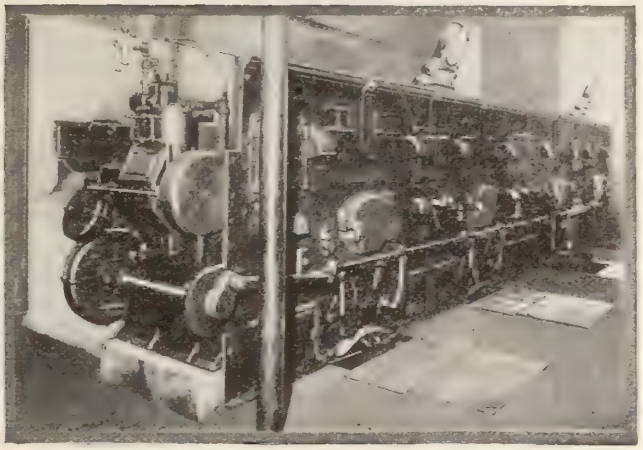
Before *and* After Installing



DETROIT'S "V" Type Stokers

In the Plant of The Mercer County Light, Heat and Power Company GREENVILLE, PA.

AFTER many disappointments and troubles with their old furnaces and careful study of mechanical stokers, The Mercer County Light, Heat and Power Company selected Detroit "V" Types for their power plant.

Four Stokers were installed early this year, and have been in continuous service since that time.

Mr. R. L. Morsman, Chief Engineer, states:—

". . . we compute that we are obtaining a saving of from 10 to 12 percent of coal over the previous hand fired method.

"We are obtaining a Boiler Horse Power on approximately 3½ pounds of coal of 13,000 to 13,500 B. T. U. This is equivalent to a little better than 72 percent efficiency, which we consider very good for every day conditions.

"The Stokers are giving excellent satisfaction and we would be very glad to recommend them to any of your prospective purchasers."

This sort of testimony, which we are continually receiving from operators of Detroit "V" Type Stokers, is indicative of our reputation in the Power Plant Field.

Catalog P contains full particulars. It will gladly be forwarded on request.

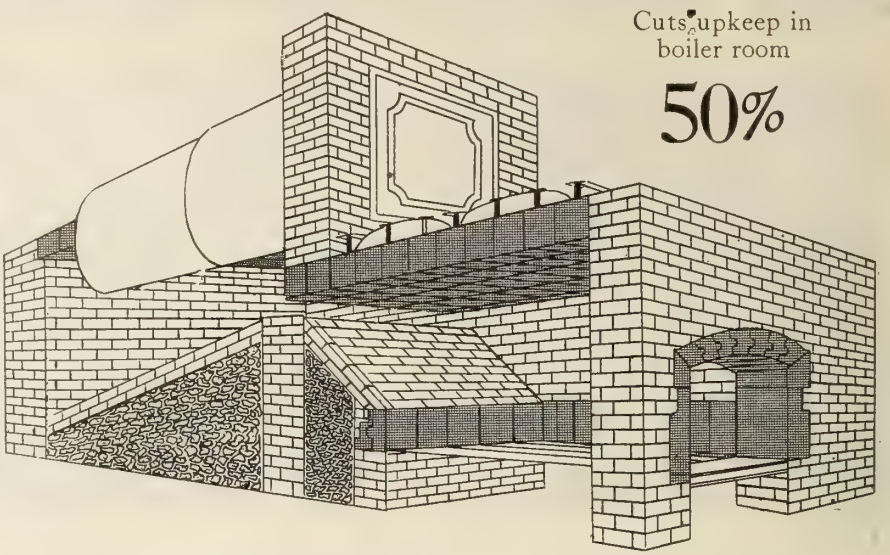
GATES Patent Furnace Linings

These are the simplest and most durable linings made. Their use materially reduces the number of joints in the furnace walls, clinkers do not readily form on their smooth and even surfaces and the tongued and grooved joints prevent air leaks, thus the linings not only last longer, but tend to promote better combustion. These blocks are interlocking and made so that any handy man can renew them without disturbing any of the brick work.



Cuts upkeep in boiler room

50%

We Manufacture All Kinds of Special Shape Fire Brick

We contract for and specialize in Boiler Setting, Furnace Building, Oven Work and all kinds of power plant brick work. **Catalogue mailed on request.**

ANY·CAPACITY ANY·PRESSURE

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

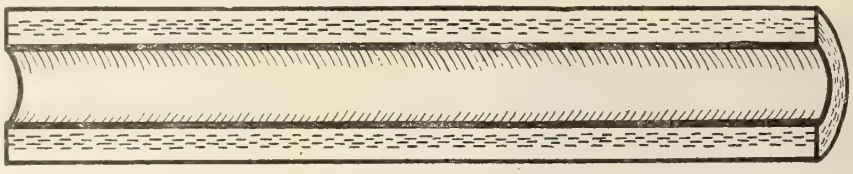
SECTION OF STEAM HOSE SHOWING THE EFFECTS OF WIRE-WINDING UNDER PRESSURE.



SECTION OF GOODYEAR STEAM HOSE UNDER THE SAME PRESSURE.

Goodyear has made Wire-Winding on Steam Hose Unnecessary

THAT the expansion of steam in steam hose had to be controlled by wire-winding has been long taken for granted by industry. Of course, the wire became bent and the hose choked up; it became too hot to handle; it was inconvenient to cut into shorter lengths; the wire cut through the cover. But it had always been so. And wire-winding seemed essential to protect hose from rough usage and from pressure bursts.

The illustration shows what wire-winding does to steam hose. Under the heat and pressure of use, the hose expands faster than the wire. Bulges and blisters form. The tube cracks and the fabric is weakened.

Goodyear has made wire-winding on steam hose unnecessary. Goodyear has developed a hose fabric strong enough to control steam under high pressure—tough enough to insure long service *without special winding or covering.* Add an inner tube of special compound to resist heat and a tough cover—there you have the story of very long service and very low final cost.

The high quality of Goodyear Steam Hose—the unusual construction, developed solely to meet the severe conditions under which steam hose is used—are but samples of what you will find in all Goodyear Industrial Hose.

Goodyear has scientifically developed a hose for every industrial use. Samples of this hose, and the advice of a trained technical man, are yours for the asking—without obligation. Phone, wire or write the nearest branch.

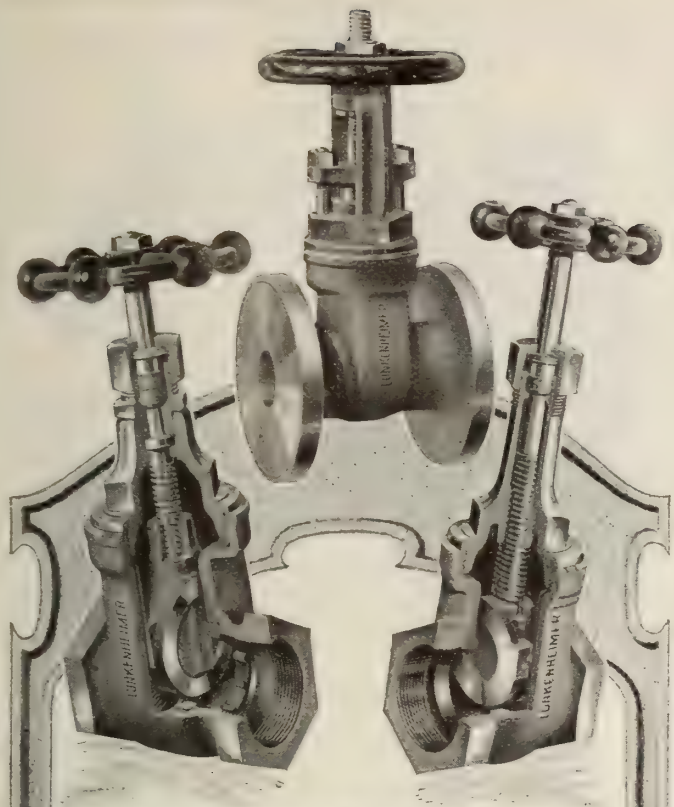
INDUSTRIAL HOSE



LUNKENHEIMER BRONZE GATE VALVES

have full straightway opening; are double-seated and will take pressure from either end.

Bodies are heavy to resist pipe strains and the valves seat tight without undue pull on the hand wheel.

The DOUBLE DISC type has a ball and socket bearing between the discs, making them self-adjusting and the discs are accurately guided by ribs in the body. Sizes, ¼ to 3 inches, inside screw for working steam pressures up to 150 pounds.

In the WEDGE DISC type, the seats are finished to the exact taper of the disc faces and all parts are renewable, including the SEAT RINGS on sizes one inch and larger. Made in sizes ½ to 3 inches, inclusive, with inside screw and 1 to 3 inches with outside screw and yoke for working steam pressures up to 200 and 300 pounds.

The material and workmanship are of that high order which characterizes all Lunkenheimer products.

Buy the best—they are the cheapest.
Your local dealer can furnish them; if not write us.

Write for Booklet No. 574-D.C., and list of regulations covering Lunkenheimer Products.

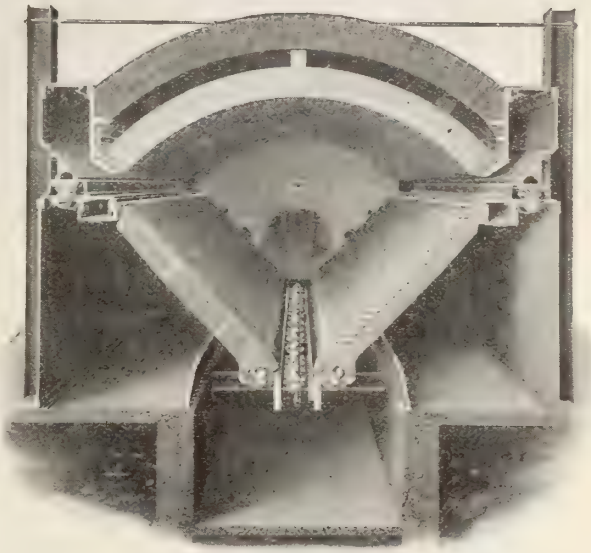
MURPHY AUTOMATIC FURNACES



STOOD the Test of Time

The Murphy Furnace is the pioneer among stokers. It is one of the oldest—and one of the best; 37 years of successful operation—and still going strong. Today over 6,000 boilers are fired by Murphy Furnaces.

Remember that during that time a great many manufacturers have sprung up and died. Time tells—the principle must be sound—the operation successful.

Our engineers have gathered a store of useful information. The Catalog HM-1 is yours for the asking.

For information on RILEY UNDERFEED STOKERS for large boilers, see last month's advertisement or send for RILEY STOKER Catalog "HR-1".

TAG

Indicating Thermometers in the Power Plant

Constant temperature readings are vital to economical power plant operation, and TAG Industrial Thermometers are made especially for power plants.

They are easily attached to steam inlet or exhaust, feedwater or condenser—any place, in fact, where a temperature reading is wanted.

There are many forms of connection; fixed thread, union or separable socket. The glass tube is seasoned so that it cannot change; the mercury in the bulb is the only thing that expands.

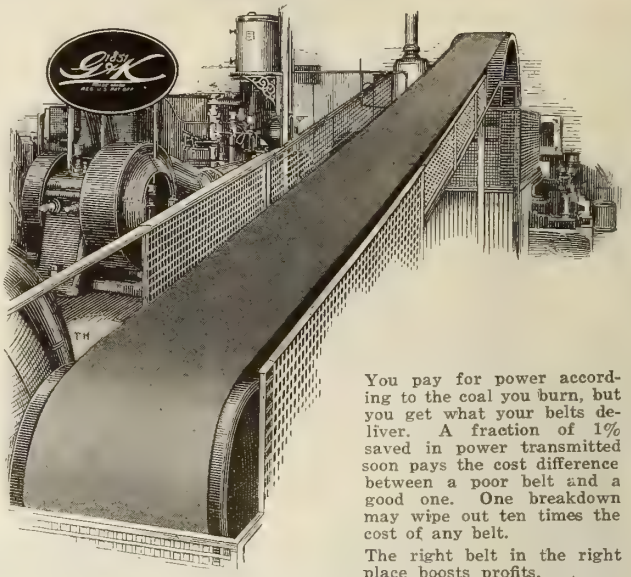
C. J. TAG LIABUE MFG. CO.
TEMPERATURE ENGINEERS
18-88 Thirty-Third St. Brooklyn, N.Y.

The following guarantee covers TAG Industrial Thermometers:

Accuracy—Absolute and Constant
Construction—Highest Grade Workmanship
Material—Most Durable for the Particular Application, and Insurance against loss by breakage in transit.

Catalog P-405 on request.

THE POWER YOU PAY FOR



You pay for power according to the coal you burn, but you get what your belts deliver. A fraction of 1% saved in power transmitted soon pays the cost difference between a poor belt and a good one. One breakdown may wipe out ten times the cost of any belt.

The right belt in the right place boosts profits.

Among Graton & Knight Leather Belts there are right belts for every drive, belts that will deliver maximum power year in and year out without a halt.

Our booklet, "Standardized Leather Belting," explains how to find the right belt. A copy will be sent you upon request.

Rollers too Hard to Machine

ANOTHER remarkable feature of the

Jeffrey

Pivoted Bucket Carrier

is the extreme hardness of all wearing parts. For example, the bore of Chain Rollers is ground to size on a special grinding machine. The tough, white iron is so hard that it resists the action of high-grade machine tools.

The Jeffrey Carrier has many other unusual features that make for Reliability and Long Service.

Every worth-while improvement has been incorporated in the design which is the climax of our 20 years' experience as builders of Coal and Ash Handling Machinery.

Our Engineers will gladly study your plant and make recommendations. Catalog No. 210 will give you an excellent idea of the JEFFREY Carrier and its possibilities. Write today.

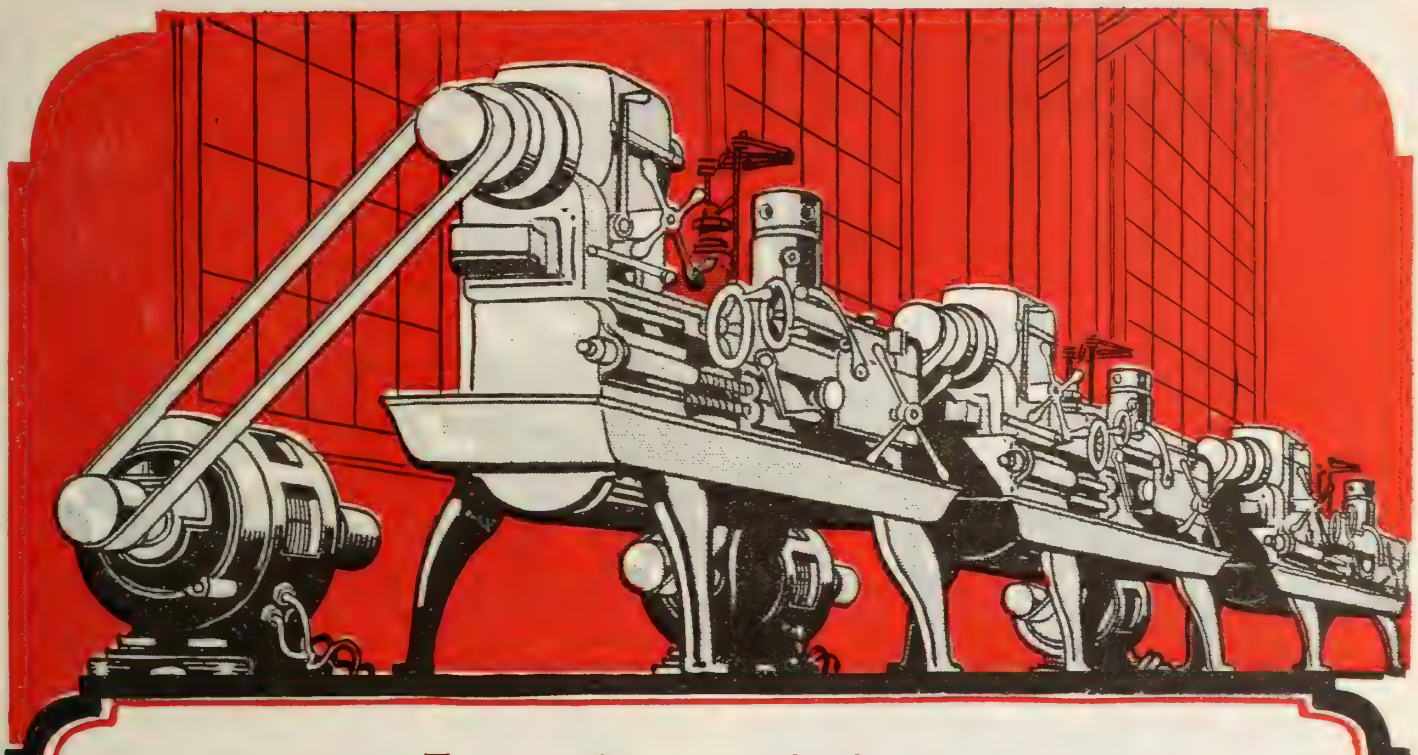
Practically Frictionless

In Cotton Tubes



Every Ounce of Energy

AMONG the most important factors in keeping production up and operation costs down is the efficient transmission and utilization of every ounce of energy developed by power-generating machinery. A high friction load means a corresponding reduction in the power available.

The burden of this rests entirely on the correct lubrication of every machine, axle, pulley and shaft. *Nothing but scientific lubrication throughout your entire mechanical equipment will enable it to contribute its full quota to the success of your business.*

Imperial Lubricants are specially designed for each type of machine under actual service conditions. Their use will bring increased income through greater production, and reduced expenses through smaller depreciation of machinery.

Imperial Lubricants are prepared with infinite care. Each one has real merit as its recommendation. There is the proper lubricant for every individual part of your machinery. They are Canadian made, and their high, uniform quality is assured by the use of only the finest crudes.

Imperial Lubrication Engineers will be glad to consult with your own engineer or mechanical superintendent in deciding the proper lubrication of your machinery. The benefit of their knowledge and experience is yours without charge or obligation.

Burn Low Grade Coal

CUT FUEL COSTS

Burn Refuse

This winter high-grade coal promises to be scarcer than ever, thus higher priced. Many power plants will have to substitute low-grade fuel and to many this will mean the installation of extra boilers to supply the required steam.

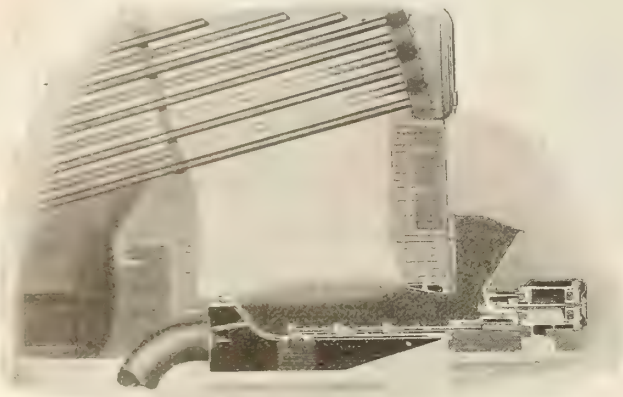
"Jones Underfeed Stokers" will burn low-grade fuel, keeping up your steam pressure and meeting your peak loads without installing extra boilers.

We furnish special stokers to burn Lignite

SMOKE ABATEMENT

The "Jones Stoker" assures proper combustion of fuel which means that the stack will be free from smoke.

The Jones simple construction means durability, no parts move in contact with the fire—no grates to burn out—no sifting of fine coal to the ash pit.



A Jones Underfeed Stoker setting under Water Tube Boiler.

The Jones Underfeed Automatic Stoker

pioneered and developed commercially the Underfeed principle of firing, which is to-day recognized as the most efficient method of stoking.

THE KEY TO SUCCESS

EXPERT KNOWLEDGE

OF THE PROCESS OF COMBUSTION AND BOILER ROOM MANAGEMENT is absolutely essential for success in the power plant engineering field today. The man that the big fellows are looking for is the man who, first of all, can utilize the last heat unit in the coal he burns under his boilers.

The Hays School of Combustion has provided the means by which this expert knowledge can be easily acquired by any one who will spend a few hours of his spare time to master the simple, interesting and easily understood lessons provided. The correspondence method of instruction is used, which permits any man to proceed according to the time available and his previous study of the subject. It teaches you all about the most up-to-date practice, all about fuels and how to obtain combustion efficiency, and all about boilers and furnaces and how to operate them economically. Every essential detail is supplied in this course, and in such a manner that you will find it more interesting than your favorite novel.

GREATER REWARDS

ARE WITHIN THE REACH OF THE COMPETENT COMBUSTION ENGINEER at the present time than in any other line of endeavor connected with the power plant field. Men who can select the proper kind of coal for each particular plant and condition, determine how it can be most efficiently burned, and, in the final analysis, **GET RESULTS**, with a minimum expenditure for fuel, are the fellows for whom the demand is, and will be, unlimited. If you want to be listed with the top-liners, this is your opportunity.

For the fireman, steam engineer, master mechanic or technical man, or for the young man seeking a lucrative calling, the sure job and the big pay, with all the accompanying advantages, there is no field so ripe—where the prospect of rapid advancement and quick returns is so promising. Employers are seeking greater efficiency in the operation, equipment and supervision of power plants. They want better trained men in the plants and more combustion engineers for consulting and construction work, giving opportunity for every grade of ability. If you have the foresight and ambition to train yourself, the opportunity is yours.

The course is written and arranged by Jos. W. Hays himself—in his well-known interesting and effective way of conveying the desired information. There is not a dull or uninteresting line in the whole course. The practical value of the course is unquestionably assured by the staff of Advisory and Reviewing Editors given below.

Joseph Harrington — David Moffat Myers
Fred R. Low
Arthur L. Rice — Prof. S. W. Parr

Electrical Energy Generating Stations—I

Dealing With the Design of Power Stations, Both From the Electrical Standpoint and From That of the Prime Mover.

By TERREL CROFT
(Copyright; all rights reserved by the author)

THE procedure which will be followed in describing Electrical Energy Generating Stations is this: First, certain general considerations relating to all generating stations, regardless of the types of their prime movers, will be treated. Second, the adaptability of each of the different classes of prime movers: (a) steam, (b) internal combustion engine, and (c) hydraulic, will be described. Third, stations having steam prime movers will be studied in some detail. Fourth, stations having internal-combustion engine prime movers will be considered. Fifth, hydro-electric stations will be examined.

In Determining the Cost Per Unit of Electrical Energy Generated by a Station a number of factors must be included. Among these may be: (1) cost of fuel, if any, (2) labor cost of attendance and operation, (3) cost of supplies, such as oil and waste, (4) interest on the investment, (5) depreciation, (6) taxes, (7) insurance, and (8) repairs. How all of these factors may be recognized in estimating the total cost is indicated in the example just following. It is obvious that each specific problem must be considered on its own merits. The reasons for this are that the efficiencies of the apparatus involved, the cost of fuel, the cost of attendance and similar elements, will vary widely under different conditions.

Examples of Method of Determining Cost of Generating Energy

The following examples are quoted to illustrate the general procedure and the principal factors involved rather than to emphasize specific values. The problem is this: Which would be more economical under the conditions to be recited, to continue to operate a steam plant or to purchase electrical energy from a central station? The connected load is 275 kw. The maximum demand (maximum load) is 230 kw. The annual energy consumption is 62,700 kw.-hr. There are two generators in the plant, each driven by its own steam engine. No. 1 is a 200-kw. unit. No. 2 is a 75-kw. unit. The charge which the central station would make would be based on (1) a "demand" or "readiness-to-serve" charge of $2 per month per kw. of connected load and (2) an additional "energy" charge of 0.9 cts. ($0.009) per kw.-hr. consumed. All of the connected apparatus is direct current, hence, if central-station energy is purchased, it must be direct current or be converted into direct current for utilization.

Solution.—The following comprises the solution, submitted by H. Berkeley Hackett, to the above example. Owing to th values submitted for maximum demand and monthly energy consumption, it would be erroneous to assume the 10-hr.-day service during 26 days per month, which is the customary working period in manufacturing industries, since on this basis the average hourly load would exceed the maximum demand. In order, however, to reach any conclusion it is necessary to decide upon a daily operating period, consequently it will be assumed that the plant in question operates continuoulys during 365 days per year. While this assumption may not represent actual conditions, it will at least afford a basis for demonstrating the method of computing the yearly cost of generating energy and comparing same with central-station service.

The first step will be to find the boiler capacity required to meet the peak load conditions, in order that fixed charges on these units may be properly accounted for. With a maximum demand of 230 kw., the probable "water rate" of the large engine will be 40 lb. of steam per kw.-hr., consequently the hourly steam consumption under these load conditions is: $230 \times 40 = 9{,}200$ lb. plus 10 per cent. for auxiliaries, pipe line losses, etc., or a total of 10,120 lb. per hr. that the boilers must supply during maximum-demand periods.

Assuming that the steam pressure is 130 lb. gage and that the temperature of the feed water entering boilers is 200 deg., each pound of feed water must receive in the boilers 1024.8 heat units to convert into steam at the assumed pressure. Therefore, the boilers must be capable of furnishing: $10{,}120 \times 1{,}024.8 = 10{,}371{,}000$ heat units per hr. Since a boiler horsepower is equivalent to 33,500 heat units, the boiler capacity required will be: $10{,}371{,}000 \div 33{,}500 = 310$ h.p. Three 150 h.p. water-tube boilers will therefore be considered in estimating the installation costs.

The second step in the calculation will be to determine the yearly coal requirements. With a monthly consumption of 62,700 kw.-hr., the average hourly load of 24-hr. service will be: 62,700 ÷ (24 × 30) = 86 kw. approximately. To allow for load fluctuations on engines and boilers, it will be assumed that the water rate of the engines is 45 lb. of steam per kw.-hr., and that the boilers evaporate 6 lb. of steam per lb. of coal. This evaporation corresponds to 51 per cent. boiler efficiency, assuming the heat value of the fuel to be 12,000.

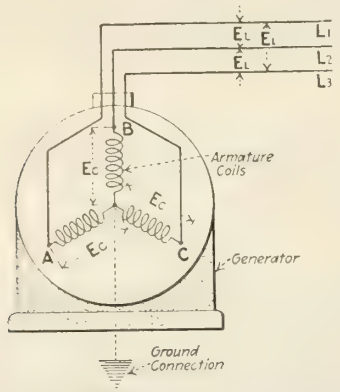

FIG. 1—DIAGRAMMATIC REPRESENTATION OF A STAR OR Y-CONNECTED THREE-PHASE GENERATOR.

On a basis of 8,760 hr. per year, the total yearly steam requirements, including 10 per cent. for auxiliaries, pipe-line losses, etc., will therefore be: 86 × 45 × 8,760 × 1.1 = 37,291,000 lb., and since each pound of coal evaporates 6 lb. of steam, the coal necessary to evaporate this quantity of steam is : 37,291,000 ÷ 6 = 6,215,100 lb., or 3,110 short tons.

Having determined the boiler capacity and the yearly coal requirements it is possible to approximate the yearly operating costs, as given in the following tabulation:

Installation Cost

Apparatus	*Cost*	*Sub-totals*
One 120-h.p., 4-valve engine (erected)	$2,600	
One 320-h.p., 4-valve engine (erected)	5,800	
Foundations	750	
Three 150-h.p. water-tube boilers (erected)	7,500	
Steel stack foundation—breeching erected	2,000	
Feed-water heater—boiler feed and house pumps	1,000	
Piping—covering separators, tanks, etc.	4,000	$23,650
One 75-kw. direct-current generator erected	1,100	
One 200-k.w. direct current generator erected	3,000	
Switchboard and wiring	1,700	5,800
Total cost of plant	.....	$29,450

Generating Cost

Interest on $29,450 @ 5 per cent.	$1,470	
Depreciation on $29,450 @ 6 per cent.	1,770	
Taxes, insurance, etc., on $29,450 @ 1 per	295	$3,535
Fuel, 3,110 tons @ $3	9,330	
Labor (5 operators)	4,600	
Ash hauling	100	
Oil waste, etc.	300	
Maintenance and repairs	600	$14,930
Total annual cost of generating 67,200 × 12 = 752,400 kw.-hr.	.....	$18,465
Cost per kilowatt-hour, in cents = 18,465 ÷ 752,400 =	.....	2.46

Cost of Central-Station Service

The connected load is 275 kw. The primary charge will be $2 per month. The average monthly energy consumption of 62,700 kw.-hr. will be at the rate of 0.9 cts. per kw.-hr. If a rotary (synchronous) converter is installed, the customer will probably be required to pay the conversion losses. With a converter efficiency of 90 per cent., the monthly bill charged against the consumer will therefore be: 62,700 ÷ 0.9 = 69,500 kw.-hr. The annual cost of purchased power will therefore be about as follows:

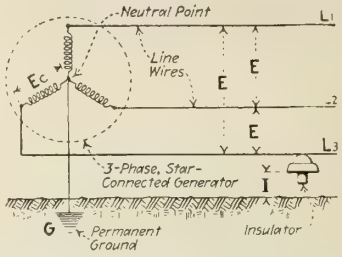

FIG. 2—ACCIDENTAL GROUND ON A GROUNDED-NEUTRAL SYSTEM.

Installation Costs

One 250-kw. rotary converter	$3,000	
Switchboard	1,700	
Total installation cost	.....	$4,700

Operating Cost

Interest, depreciation, etc., @ 12 per cent. on $4,700	$560	
Primary charge—275 × 12 months × $2	6,600	
Current charge—69,500 × 12 × $0.009	7,500	
Night and day attendant	1,700	
Oil, waste, repairs, etc.	70	
Total yearly cost of 69,500 × 12 or 834,000 kw.-hr.	.....	$16,430
Cost per kilowatt-hour in cents	.....	1.97

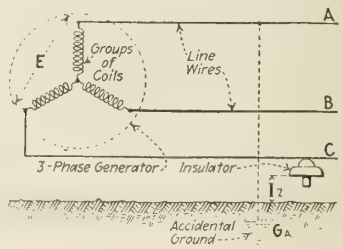

FIG. 3—ACCIDENTAL GROUND ON AN UNGROUNDED NEUTRAL SYSTEM.

In the above estimates no consideration has been given the question of heating. Should the conditions demand this requirement, it will be necessary to make certain additional charges against the central-station estimate in order to obtain a true comparison of power costs. These charges would consist of interest and depreciation on boiler capacity for heating, corresponding to the boiler capacity, available in the private plant for this purpose. Also, a charge for fuel for generating steam, equivalent in amount to the exhaust steam from the engines of the private plant that could be utilized in the heating system. There would be a further charge for labor, maintenance, supplies, etc., in connection with the operation of boilers for heating.

Depreciation of the Equipment of an Electric Plant

In general, plant and sub-station buildings may be assumed to have a useful life of about fifty years, making the average depreciation about 2 per cent. To boilers, piping, generators, electrical equipment, etc., lives of twenty years are assigned. Of these, boilers, piping and generators have net salvage values of 4 to 6 per cent. at the end of that time, thus making their rate of depreciation from 4.7 per cent. to

4.8 per cent. per annum. Allowing 10 per cent. salvage value for electrical equipment, the rate of depreciation becomes 4.5 per cent. Storage batteries, with a useful life of twenty years, go out of service with a salvage value of 17 per cent., making the net depreciation 4.15 per cent. per year. Poles and pole-line equipment are assigned values of 12 per cent. at the end of twenty years' service, resulting in a depreciation rate of 4.4 per cent. Wire, after sixteen years' estimated usefulness, has the high scrap value of 40 per cent., making the depreciation rate 3.75 per cent. Line transformers and customers' meters may be assumed to have the same life as the other electrical equipment named, twenty years, but at the end of that time they have a salvage value of 10 per cent., making the net depreciation rate in the case of these instruments 4.5 per cent.

The Location of a Generating Station is a thing which should be considered most carefully, because if the station is not located intelligently, the cost of the energy generated and delivered by it may be excessively high. In this connection, the following items* are of importance: (1) accessibility, (2) coal and water supply, (3) stability of foundation, (4) facilities for extension, (5) cost of real estate and taxes, and (6) situation should be such that the output of the plant may be effectively utilized.

The following table illustrates a logical and systematic method of tabulating the fixed-charge data when an energy-cost determination is being made. This table shows the values assumed by T. B. Hyde in his solution of the example above proposed. For this complete solution refer to the number of the magazine cited in the footnote.

STEAM PLANT (*Energy Generated*)

A	B	C	D	E	F	G	Fixed charges (per cent.)					X
							I	J	K	L	M	
Item	Equipment	Number	Size	Unit	Unit cost	Total cost	Interest	Depreciation	Insurance, taxes	Maintenance (repairs)	Total	Fixed charges per year
1	Boilers	3	150	B.H.P.	$14.00	$6,300	5	5	1½	6½	18	$1,134
2	Engine	1	320	I.H.P	11.00	3,520	5	5	1	3	14	493
3	Engine	1	120	I.H.P.	10.00	1,200	5	5	1	3	14	168
4	Generator	1	200	K.W.	12.50	2,500	5	5	1	1	12	300
5	Generator	1	75	K.W	13.35	1,000	5	5	1	1	12	120
6	Building					9,000	5	3	1	1	10	900
7	Feedpump					200	5	7	1	3	16	32
8	Feed-water Heater		400	H.P.	1 50	600	5	5	1	3	14	84
9	Piping					2,000	5	7	1	3	16	320
10	Total											3,551

ELECTRIC PLANT (*Energy Purchased*)

11	Building					$3,000	5	5	1	1	10	$300
12	Synchronous converter					2,000	5	5	1	1	12	240
13	Total											$540

Note—The station should, all things being equal, be easily accessible so as to facilitate the delivery of fuel, stores and machinery, while it should be so located that the ashes may be easily removed. If possible, the station should be so located that it may be reached by both rail and water.

The Advantages of Centralization, that its, he advantages which accrue through the concentration of generating equipment into one large plant rather than having it scattered among a number of small plants, may be recited thus†—(1) It is possible to distribute the power economically, (2) because of the diversified nature of the load it is possible to operate the system with a better load factor, (3) purchasing supplies and spare parts at a central point is a decided economic advantage, (4) the centralization of management and operating force reduces the overhead expenses, (5) it is possible to serve certain classes of customers whom the small individual plant could not afford to serve, (6) the lower cost of production, due to centralized service, makes it possible to offer lower rates, (7) consolidation of interests makes possible the financing of improvements, of substitution of new for obsolete apparatus and the extension of service into new territory, and (8) better regulation and better protection can be provided.

†The Location of Power Plants, by J. E. Kearns, of the Boston Edison Company.

General Considerations Relating to the Generating Stations

Direct-Current Voltages and Systems may be divided into two-wire and three-wire systems. Two-wire systems (which are, ordinarily, desirable only for electric-lighting service where the power is transmitted over very short distances) usually

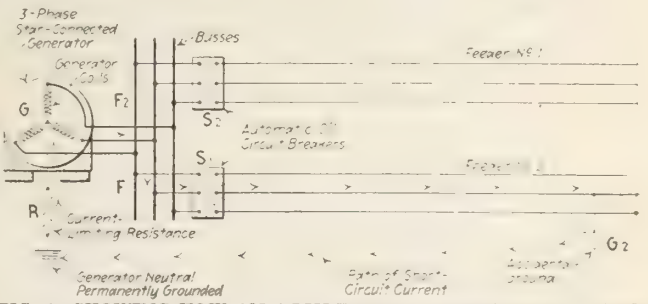

FIG. 4—SHOWING HOW AN ACCIDENTALLY GROUNDED FEEDER WILL DISCONNECT ITSELF FROM THE GENERATOR ON A GROUNDED-NEUTRAL SYSTEM.

operate at 110 volts because 110 volts is, due to economic reasons, the most desirable pressure for operating incandescent lamps in multiple. Occasionally, in a direct-current installation, where the power must be transmitted for a distance of possibly something under a mile for direct-current motors, a 220-volt direct-current system may be installed. If this is done, 220-volt incandescent lamps are used. It is seldom that a two-wire direct-current system is now installed for general electric lighting and power service. Usually, because of the economics which result therefrom, a three-wire system is used. The pressure between the outer wires is 220 volts, and between the neutral and each of the outers, 110 volts. With this system, the incandescent lamps can operate on 110 volts and the motors on 220. The stations in many office buildings, industrial plants and small towns, generate on 110-220 volts three-wire systems. For urban railway service, the standard direct-current pressure is 600 volts. Pressures as high as 1,200, 2,400, 1,500 and 3,000 volts have been applied recently for interurban and trunk line railway service.

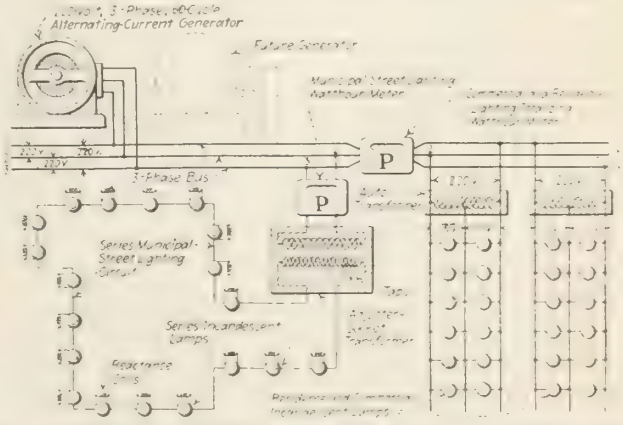

FIG. 5—GENERAL SCHEME OF GENERATION AND DISTRIBUTION FOR A TOWN OF ABOUT 1,000 INHABITANTS OR LESS

The Generating of Alternating Voltages is now, in stations serving large cities or considerable loads of any character, the usual practice—because of the economics which result therefrom. Then, if at any location on the distribution system, direct current is required, the alternating can be converted into direct voltages by using motor-generators or synchronous converters. A large percentage of all generating stations which have been installed recently—this includes many small stations as well as large ones—generate only alternating voltages.

Practically all Alternating-Current Stations Generate Three-Phase. (This refers to stations which have been installed

recently. There are still a number of two-phase stations and a very few single-phase stations in operation.) The reason for this is that three-phase generating and converting apparatus is the most economical and energy can be transmitted more economically with the three-phase system than with any of the others which are utilized directly. The three-phase can be readily transformed or converted into power of some one of the other systems if desirable.

Note.—Even if a large proportion of the output of a station must be transformed or converted to render it available for utilization, it is usually most economical to generate only one kind of energy. That is, for most cases in a station of any size, only three-phase alternating power should be generated. The reason why this plan is ordinarily followed is that with it the generating units can all be operated at

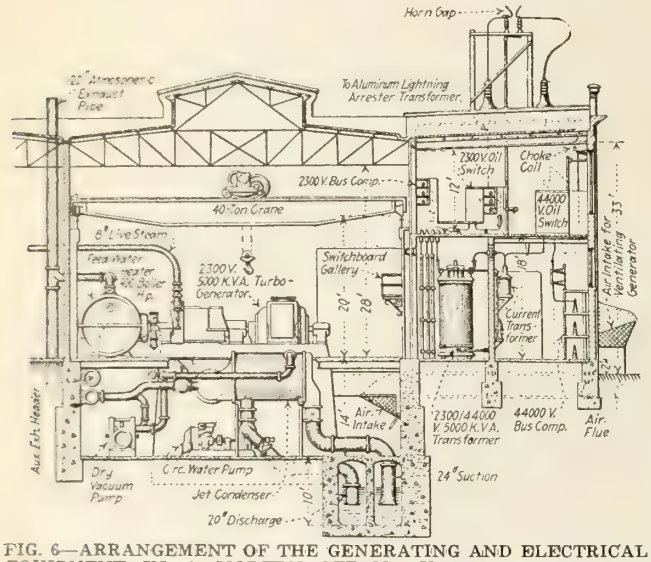

FIG. 6—ARRANGEMENT OF THE GENERATING AND ELECTRICAL EQUIPMENT IN A MODERN STEAM TURBINE GENERATING STATION. (After E. A. Lof, in "Coal Age," Feb. 6, 1915.

greater loads. That is, the individual load factors of the generating units can be maintained at a maximum, due to the advantage that may thereby be taken of the diversity element. Furthermore, where only one kind of power is generated, the investment which must be tied up in reserve apparatus may be a minimum.

Three-Phase Generators are Usually Star Connected* (Fig 1.) because of this method of connection for a given voltage, El (Fig. 1) between line wires, the voltage Ec across each set of armature coils is less than it would be with a delta-connected generator impressing the same line voltage. In view of this, the number of turns in the star-connected generator coils is, for a given line voltage, smaller. Hence conductors of a correspondingly larger diameter can be used for them than would be necessary with a delta-connected machine. Thus a more sturdy and satisfactory mechanical structure results. Furthermore, certain difficulties, due to local currents circulating in the machine windings, which may occur with the delta, are eliminated with the star connection.

Both Grounded and Ungrounded-Neutral Systems are used. Which is preferable must be determined in each specific case after due consideration has been given to the factors involved. There are two reasons for grounding the neutral. One is to limit the voltage, between line and ground, which may be impressed on the insulators and apparatus.

Explanation. If a neutral is grounded, as at G, Fig. 2, it is evident that the electric stress imposed on the insulator at I, between line wire L3 and ground, can never be greater than the voltage Ec which is 0.58 of the line voltage, E. If, however, the neutral is ungrounded as in Fig. 3, and an accidental ground, Ga, occurs, then the line voltage is impressing on the insulator at I2 between the line wire, C, and ground. The line voltage in a three-phase system always equals 1.73 times the voltage to neutral. (The voltage to neutral is shown by Ec in Fig. 2.)

*Some of the material which follows is based on data contained in the article "Generating Stations and Some Features Governing Their Design," by E. A. Lof, of the General Electric Company, published in "Coal Age," Feb. 6, 1915.

The other reason for grounding a neutral is to insure that one of two or more sets of feeders will, by the action of the overload oil circuit-breaker inserted in it, promptly disconnect itself from the station if a ground occurs on that feeder.

Explanation. If an accidental ground, G2 (Fig. 4) occurs on a feeder, F1, supplied by a generator having a grounded neutral, a current will flow through the accidental ground as shown by the dotted arrows. This ground will be of sufficiently low resistance so that the current which flows will be of great enough intensity—(amperage)—to immediately operate the automatic oil switch or oil circuit-breaker, S1. This will isolate F1 from the system. If the neutral were not grounded, the attendants in the station where the generator G was located might not be informed promptly of the existence of the accidental ground, G2.

It follows that, if only one feeder extends from a station to a given load and that continuous service is essential, grounding is probably undesirable. If on the other hand, two or more feeders extend from the station to the same load, then grounding may be desirable. As a rule, it is good practice to omit the grounding of generators where only one or two feeders extend from the station, unless the system operates at a very high voltage. Where the neutral is grounded merely to insure the automatic disconnection of a feeder in the event of a ground on it (Fig. 4), a resistance, R, may be inserted between the neutral point of the generator and ground, to prevent the flow of excessive current in case of an accidental ground, G2, on the line. Such a resistance should be so proportioned that it would permit enough current to flow to operate the automatic oil switches but would at the same time prevent the flow of a dangerously-large current.

The Voltages for Alternating-Current Generators vary with the conditions under which the plant operates. Occasionally where a very small plant serves only an incandescent-lighting load, the generator voltage is 110. More frequently a pressure of 220 is adopted for small plants which serve a three-wire system, the three-wire, 110-220 volts pressures (Fig. 5) being obtained with balance coils located at points near the load. Sometimes, in industrial plants where a considerable number of alternating-current motors are used, 480-volt three-phase generators are installed. Generators for 2,200 to 2,400 volts, three-phase, are very frequently used in towns and small cities for serving a general lighting and motor load. In large industrial plants, three-phase 6,600 volt generators are ordinarily used. A pressure of 13,200 volts is the highest for which it is deemed desirable in the United States to wind alternating-current generators. Hence, a great many machines generate

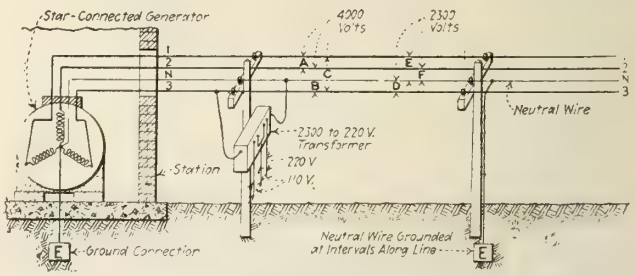

FIG. 7—THE FOUR-WIRE, THREE-PHASE SYSTEM.

at this pressure. Where the transmission distance is sufficiently short, it is economical to use 13,200 as the transmission voltage. In many plants the generation voltage is 2,300 or 2,400 (Fig. 6) and this pressure is raised with transformers to one suitable for the long-distance transmission. The four-wire, three-phase system (4,000 volts between line wires, Fig. 7 and 2,300 volts to neutral) is now being used extensively for local distribution for light and power in cities. In any case, the generator voltage which should be selected is largely a matter of economics.

[To be continued in February 20 issue]

An Iowa inventor has obtained a patent upon a unicycle that is driven by an electric motor and prevented from falling by gyroscopic fly wheels.

Protecting Boiler Drums From Overheating

Common Causes for Bulging—The Superheater—The Three-Pass Setting—The Protection of Boiler Drums—Secondary Combustion

(Reprinted by courtesy *The Locomotive*)

A BULGED spot on a boiler shell is not an uncommon occurrence. We associate it usually with the fire sheets of horizontal tubular boilers, the crown sheet of locomotive boilers, and in general with the furnace tops of internally fired boilers. The cause may be either shortness of water or an accumulation of oil, mud or scale. When a steel plate or a steel tube is exposed to the hot products of combustion on one side, and is covered with water on the other side in a well designed boiler, heat is transmitted from the hot gases and from the radiating fuel bed through the metal to the water at a sufficiently rapid rate to keep the temperature of the metal well below the range at which it begins to lose its strength and becomes soft and plastic. If, however, some substance comes between the metal and the water which cannot remove the heat from the metal as fast as it is received from the fire and the hot gases, the metal becomes gradually hotter till a point is reached at which it is no longer able to withstand the stresses imposed by the steam pressure within the boiler and the plate or tube swells out into a bulge. If the bulged metal continues to receive heat at a faster rate than it can dispose of it the bulge increases in size and the metal wall gets thinner and thinner until it ruptures at the weakest point.

Common Causes for Bulging

There are many different conditions which may result in a bulged spot in a boiler, and since the portion of the boiler directly exposed to the action of the flame and combustion products is usually below the normal water line, we are apt to look for this condition only at such points. The most common cause for bulges below the normal water line of a boiler is of course a deposit of some sort of heat-resisting material on the water side of the metal. This may be an oil film or it may be a deposit of mud or scale matter from the boiler water. In either case if it provides sufficient hindrance to the flow of heat, a bulge will result. These causes have been discussed in the columns of "The Locomotive" for years, and they are very familiar to engineers. Another common cause for bulging and rupturing of boilers is found in some abnormal working condition which permits the waterline to become dangerously low. Under these circumstances as soon as steam and not water covers the surface of metal exposed directly on the opposite side to the heat of the products of combustion, overheating of the metal which will result in bulging and rupture is likely to start because heat cannot flow as readily through a metal and into steam as it can flow through the same metal and into water.

Superheating Surface

To be sure superheaters are made in various ways with special provisions for the rapid absorption of heat by the steam and for considerable reserve strength to resist the tendencies to bulge on the part of the metal, in which heat can be safely and profitably transmitted directly from the hot gases to steam through metal. It is also true that a properly designed vertical fire tube boiler may have a portion of the upper end of the tubes exposed on the one side to the steam and on the other to hot gases, with no serious results. In general, however, a portion of a shell or drum of a boiler, whether of the fire-tube or water-tube type, which is exposed to combustion products on one side and is not covered by water on the other side is apt to prove troublesome, if not dangerous.

Three-Pass Setting

Formerly it was common in some parts of the country to return the gases from an ordinary horizontal return-tube boiler from the front end after they had passed through the tubes directly back across the top of the boiler in a brick flue, of which the upper surface of the boiler shell was a floor, to a stack connection at the back. This arrangement has been known locally as a three-pass setting. It probably succeeded in running without serious injury to the boiler (when it did so succeed) chiefly because the gases were pretty well cooled before they emerged from the tubes at the front end and also because as the boiler shell formed the bottom of the third pass, it must inevitably become heavily blanketed with soot and fine ash in an exceedingly short time. Soot and ash are rather better insulators to heat flow than many forms of pipe covering, and so the top of the shell usually became protected with soot. When it is remembered that if soot enough was deposited on the boiler top to protect the shell plates there would certainly be enough of it to practically prevent any possible economy through the additional absorption of heat from gases by the steam. Also since the supposed extra absorption of heat was the only reason for providing the extra gas pass, a matter of some expense and much inconvenience as such a pass greatly complicates the provision of proper and accessible manholes and the location of a safety valve close to the boiler shell, there is no great difficulty in seeing why its use is rapidly declining even in the regions where it had become a nearly standard method of installing boilers.

The Protection of Boiler Drums

When horizontal tubular boilers are set, care is taken that the brickwork of the settings shall come close enough to the boiler shell so that the points can be tightly packed with asbestos rope. The line at which the brick setting and the shell are joined through this packed joint is about where a horizontal plane through the horizontal diameter of the head would cut the shell, and this is several inches below the usual working water line. In the event of low water several rows of tubes would be exposed to the fire before any unprotected portion of the shell comes in contact with hot gases. However, in some sorts of water-tube boilers the settings are so arranged that parts of the space open to the gases are in contact with portions of the surface of steam drum which are not always covered with water on the steam side. This condition may be aggravated at times of heavy load by the fact that the water line is not uniform throughout all parts of a water-tube boiler, but may rise, due to the effect of the rapid circulation in some of the tubes and drums, or in some other portion of the boiler, only to correspondingly fall at other points. The amount of this rise and fall varies with the rapidity of the circulation and the load on the boiler. A further condition to be reckoned with is the fact that although where the rate of combustion is moderate and the furnace conditions good, combustion may be completed long before the gases reach the relatively out-of-the-way corners where the shell surface is exposed above the water line. Still, under overload conditions, or with poor firing, an entirely different set of circumstances may arise.

Secondary Combustion

It is not uncommon for a portion of the fuel bed to give off combustible gas in a solid stream at a rapid rate. This solid stream may easily pass through a considerable part of the combustion space without burning. It will do this for example if it is not properly mixed with air, for gas cannot burn without air, no matter how hot the surroundings. If such a stream of hot combustible gas gets up into the corners of the setting and there finds air which is perhaps leaking through small cracks in the brick or tile, it will often burst into flame and burn strongly at these points, notwithstanding that it has come a long way from the main part of the fire. Such burning of combustible gas, when boilers are being forced, on coming in contact with air, is the thing which is occasionally seen as a flame at the top of the stack, especially in the case of gas retorts and foundry cupolas, and is known as secondary combustion. It should be clear that if secondary combustion occurs in a corner of a boiler setting alongside of a portion of the boiler shell and above the water line, serious and perhaps dangerous bulging of the shell is the result

to be expected, probably also followed by a more or less violent rupture. Indeed such a rupture might easily be sudden and large enough to start a boiler explosion, for once released, there would be abundant energy stored in the hot water and steam within the boiler to continue the destruction.

The Obvious Cure

In any case even if the rupture was a small one resulting only in the gradual release of the steam from the boiler, the accident would prove inconvenient and expensive. The means for preventing such accidents is simple and should be obvious. It consists merely in carefully studying the setting of a boiler to see if it is possible that the water line in ordinary operation can drop low enough to expose portions of the shell unprotected by water to the gases. If this is possible the setting should be changed immediately so that this contact will become impossible.

TWO FLYWHEEL EXPLOSIONS

On June 17, at the water and light plant of the City of Douglas, Georgia, the governor belt broke on a 200-horsepower Corliss engine and as a result the engine overspeeded and the flywheel burst. The consequences are indicated in the accompanying illustrations. Fortunately there were no personal injuries, but we are informed that the resulting property damage has been estimated at from $10,000 to $12,000.

The flywheel was 14 feet in diameter, and when it exploded two pieces, each weighing about 1,000 pounds, were thrown through the roof of the engine room and came to rest some 200 yards distant.

The accident occurred at two o'clock in the morning, and it is said that at that time the night engineer was at a well at the back of the engine house getting a drink of water. He realized that something had gone wrong and was about to return to his post to stop the engine. Before he could do so, however, the lights went out and the flywheel burst.

Another flywheel exploded on July 10, at about 11:45 p.m., at the plant of the O'Bannon Company, West Barrington, R. I. The plant was operating night and day at that time, and the accident occurred during the night lunch hour. Four persons were injured, none of them seriously, and considerable property damage resulted. The engine of which this flywheel was a part is also of the Corliss type and is of 250 horsepower. The speed was regulated by a belt-driven ball governor. The flywheel was 16 feet in diameter with a 25-inch face, and was made in two sections. It had been inspected recently and pronounced in good condition. A speed of 80 revolutions per minute was allowed, although the ordinary running speed was slightly lower than this. The wheel was of substantial construction, with ribbed spokes cast solid, a large hub, and plenty of metal and ribs underneath the face.

All of the spokes broke off quite near the rim, except one which parted near its junction with the hub. The rim broke into numerous pieces which, in flying about, tore down steam pipes, pulleys, and shafting, and demolished walls and ceilings. One of the fragments was found in an apple orchard nearly 300 feet from the engine room.

We have no definite information at this time as to the cause of this second accident, but the opinion has been expressed that something was wrong with the governor. It had been the custom for many years at this plant to remove the load from the machines during the lunch hour and to leave the engine running under governor control. This time, however, the governor apparently failed to perform its proper function.

These two flywheel explosions, which occurred within a month in widely separated localities, show that the possibility of such mishaps is ever present. Explosions of this nature are due to numerous causes, and sometimes they occur in spite of all precautions. Many of them may be prevented, however, by installing suitable safety devices and keeping the wheels and the safety devices in good working order at all times.

We are indebted to "The Travellers Standard" for text and illustrations of this article.

CONDENSERS, PUMPS, COOLING TOWERS, ETC.

Revised and enlarged Bulletin No. 112-B, entitled "Condensers, Pumps, Cooling Towers, Etc.," has just been published by the Wheeler Condenser & Engineering Co., Carteret, N.J. This bulletin illustrates the latest developments in condenser practice. It shows a surface condenser containing 50,000 square feet of surface. Sixteen condensers, of approximately this size, are now under construction. These will contain, approximately, 1,000 miles of Crescent Brand tubing drawn in the large Wheeler tube mill. The bulletin shows photographs of a number of actual installations of surface condensers. It illustrates and describes surface condensers, jet condensers, barometric condensers, the Wheeler-Edwards air pump, the Wheeler rotative dry vacuum pump, the Wheeler turbo-air pump, the patented Wheeler steam jet air pump, Wheeler centrifugal pumps for all services, jet condensers, barometric condensers, etc.

The Principles of Heat and Thermo-Dynamics

The More Elementary Principles of Heat and Thermo-Dynamics Are Here Explained in Such a Manner as to be Helpful to the Engineer Going Up for Examination

By T. H. FENNER

BEFORE going into the study of the theory of heat, a few words on the means of measuring sensible heat, or temperature, are necessary. The thermometer is merely a glass tube, placed on a graduated scale, with a bulb blown on the bottom of the tube to form a reservoir. This reservoir contains a volatile liquid, usually mercury, the rate of expansion of which is known. There are three scales in use, the most commonly used of which is the Fahrenheit scale. This scale has a zero mark, which is 32 degrees below the freezing point, and the boiling point, which is 212 degrees, or 180 degrees above the freezing point.

The Centigrade scale is the one in use for scientific purposes, and also in some countries for general engineering purposes. The zero point for this scale is also the freezing point, and the boiling point is at 100 degrees.

The third scale is called the Reaumur, the zero and freezing point of which are the same, but the boiling point is at 80 degrees. This last scale is practically obsolete as far as any engineering purposes are concerned.

It is well that the student should know how to convert a reading on one scale to the equivalent reading on either of the others, and a little thought will show how this can be attained. The number of degrees between the freezing and boiling point on each of the three scales bear a definite relation to the others. For instance, the number of degrees on the Fahrenheit scale between these two points is $212 - 32 = 180$. On the Centigrade scale it is $100 - 0 = 100$, and on the Reaumur scale it is $80 - 0 = 80$. We have, then, 80:100:180 or 4:5:9. For instance, the number of degrees on the Centigrade scale between freezing and boiling points is $\frac{100}{180}$ of those on the Fahrenheit scale. $\frac{100}{180}$ in its lowest dimensions is $\frac{5}{9}$. If we have a reading on the Centigrade scale of 40 the corresponding reading on the Fahrenheit scale would be found as follows: Let t = Fahr., and t_1 = Cent. Then $t = \frac{9}{5} t_1 + 32$.

Substituting figures, we get $t = (1.8 \times 40) + 32$, so the Fahrenheit reading will be 104 degrees. Conversely, 104 degrees Fahrenheit can be converted to Centigrade by reversing the formula. In this case the reading will be $\frac{5}{9}$ of the Fahrenheit, and the 32 degrees on the Fahrenheit scale must be subtracted from the Fahrenheit temperature before multiplying. Thus $t_1 = \frac{5}{9} (t - 32) = .55 (104 - 32) = .55 \times 72$, which gives 39.6 Centigrade. The difference can be accounted for by carrying the recurring decimal further, as for instance:

$$.5555\ (104 - 32) = 39.996.$$

The conversion from the Reaumur to Fahrenheit is made in the same way, though the proportion in this case is 80 : 180 instead of 100 : 180. The expression would thus be, if the Reaumur reading was 40, and using t for Fahrenheit, and t_1 for Reaumur:

$$t = (t_1 \frac{9}{4}) + 32$$

$$= (40 \times \frac{9}{4}) + 32$$

$$= 122 \text{ Fahrenheit.}$$

Conversely, $t_1 = \frac{9}{4} (t - 32)$

$$= \frac{1}{9} (122 - 32)$$

$$= \frac{4}{9} \times 90 = 40$$

Converting Centigrade to Reaumur is exactly the same excepting that the addition or subtraction of 32 is not necessary.

For instance, if Reaumur reads 60, then Centigrade will be $60 \times \frac{5}{4} = 75$, while the converse would be C = 75, then R will be $75 \times \frac{4}{5} = 60$.

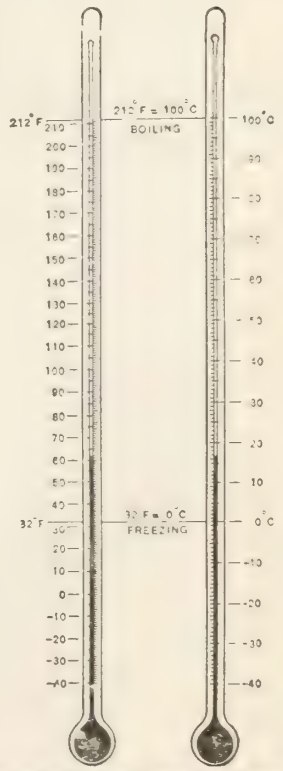
The conversion from Centigrade to Fahrenheit and vice versa will be the one most often used. It is easy to remember, as $C. = \frac{5}{9} F.$ and $F. = \frac{9}{5} C.$ The addition or subtraction of the 32 must be watched carefully. When converting from Centigrade to Fahrenheit add the 32 to the product of $\frac{9}{5}$ C., but when converting to C. from F., subtract the 32 from F. before making the multiplication. The formula is easy to remember:

$$\text{Degrees C.} = \frac{5}{9} (F - 32)$$

$$\text{Degrees F.} = \frac{9}{5} C. + 32.$$

The reason for the addition or subtraction of 32 when making conversions into or from Fahrenheit is simple. The ratio of Centigrade or Reaumur to Fahrenheit is calculated from freezing to boiling point, and while this includes zero on the first two, the freezing point on Fahrenheit is 32 degrees above zero. Hence the correction.

The ordinary mercury thermometer is not capable of measuring temperatures above 350 degrees to 400 degrees. When higher temperatures are to be taken by



COMPARISON OF CENTRIFUGAL AND FAHRENHEIT THERMOMETER SCALES.

means of a thermometer, such as a chimney or economizer gases, a modification of the ordinary instrument must be used. This special instrument is made with a seal of nitrogen gas on top of the mercury column. The effect this has is to create a pressure when the mercury expands, and this increased pressure raises the boiling point of the mercury, which at atmospheric pressure is 662 degrees. Another means of meas-

uring high temperatures is by means of the pyrometer. This is an instrument which utilizes the property of different metals to set up a difference of electric potential, when connected together through a galvanometer and exposed to the heat. This instrument is used to take furnace temperatures, etc.

Knowing that sensible heat can be can be measured by means of suitable instruments, and that heat, both sensible and latent, has a definite unit, the British thermal unit, corresponding to 778 foot pounds, we can go on to consider the different ways in which heat is transferred from one body to another.

Transference of Heat

There are three ways in which heat is conveyed from a hot body to one of lower temperature. These are by radiation, conduction, and convection, and these will be studied in detail.

Radiation is the means which is most often observed by the average person. It is the means by which we get the heat of the sun on to the earth. Rays of heat are always thrown out from a hot body, and will enter a cold body, or heat the air in its immediate proximity. It is the property of heat to radiate from a hot body which is taken advantage of in the use of heating coils in a building. It is also the property that causes the engineer immense loss if not guarded against, in places where it is not wanted. That is why boilers must be lagged, steam pipes and steam cylinders covered, and feed-water heaters protected with heat insulating or non-conducting compositions. Radiation losses are very serious and cannot be too carefully watched. For instance, the average loss per square foot of bare pipe per hour per degree difference of temperature, with steam at 100 lbs. gauge, is 2.75 B.t.u. Suppose we have a 4-inch steam pipe, the outside diameter of which is 4½ inches. The circumference of this pipe will be $4.5 \times 3.1416 = 14.137$ inches. A length of pipe 10 inches long will contain a square foot of surface. If the temperature of the steam is 338 degrees and the air 60 degrees, the difference is 278 degrees. The total B.t.u. lost per hour on this one square foot of pipe is 746. It would only take about seventeen square feet of this bare pipe to radiate as many heat units as are contained in a ton of coal. Does this make you realize the importance of radiation? However, this property of radiation is also useful as we have already seen in heating buildings. It is also seen in boiler furnaces, where the heat from the fire radiates on to the shell of the boiler, or the plates of the furnace. The firebrick lining of the furnace absorbs heat to a certain point and then radiates or reflects the heat rays striking it. When the fire is burned down and gone out this hot lining radiates the heat it has absorbed during the time the fire has been going.

Conduction

We have said that the fire radiates its heat on the plates of the boiler. How, then, does the heat reach the water contained therein. Obviously it must pass through the plates, and this process is known as conduction. The plate immediately in contact with the flame or hot gas from the fire becomes warm, and immediately begins to communicate the warmth to the molecules or layer of metal immediately in touch with it. This process goes on through the thickness of the plate till the heat applied at one side is conducted through to the other. Now various metals have different degrees of heat conductivity as they have of electrical conductivity. For instance, copper is a good conductor of electricity. That is, a current can be sent along a copper wire more easily than along an iron wire. Heat is conducted more quickly through copper than through iron or steel. Asbestos is almost a non-conductor, or the best insulator known. Following is a list of various metals, with their conducting powers. These are expressed in units of heat conducted through a plate of the material one inch thick, for one square foot surface per hour, the difference in temperature being 1 deg. on the different sides of the plate:

Copper	515
Iron	213
Lead	113
Stone	16.7
Glass	6.6
Brick	4.8

Convection

There remains the third method of heat transference, namely, convection. The heat has been radiated from the fire on to the plates, and has passed through the plates by conduction. If it is not taken away by some means the plate will go on absorbing heat until the point is reached where it will melt, or become fluid enough to be distorted. This is what happens when boiler furnaces are bulged, or collapse. However, if the plate is in contact with the water the water will absorb the heat. This will result in the water immediately in contact with the plate becoming lighter than the overlaying water. It will therefore rise, and its place will be taken by cooler water. The warm water, rising, will convey the heat to the water surrounding it, and thus a circulation or convection of heat by means of streams of warm water will be commenced. This will continue until the fire is allowed to die out. It is on the rapidity and diffusion of these streams of water that the effectiveness of a boiler greatly depends, and the design of boilers has been influenced by attempts to get the best circulation. It was on this factor that the inception of the water tube boiler depended. It is poor circulation which is the only real disadvantage of the Scotch type of boiler.

The effect of the application of heat to a body, whether a solid or fluid, or a gas, is to agitate the molecules composing the body and increase their vibrations. They thus tend to occupy more space, which causes the whole body to expand, and this expansion may be linear or volumetric. Similarly, with one or two notable exceptions, subtraction of heat causes a contraction of the body acted upon and this expansion and contraction is a very important item to the engineer.

The most notable exception to the rule of contraction during cooling is the case of water. At 39 deg. Fahr., water is at its maximum density, and addition or subtraction of heat above or below that point causes it to expand. This accounts for the terrific force exerted by water freezing in a confined space, such as a cylinder or pipe, the force exerted by the molecules of the water in expanding being sufficient to break the strongest container man can devise.

Expansion Through Heat

In the case of water expansion takes place with addition of heat until a point is reached, according to the pressure it is subjected to, where it changes its state and becomes a gas. Iron or steel or any metal expands with heat, the molecules becoming less homogeneous, or we may say, more widely separated, the earlier evidences of this being the softening of the metal. This enables it to be worked easily, being in a more or less plastic state. Carry on the heating process further, the molecules become entirely separated and the metal becomes fluid and can be poured, like water. It changes its state. Gases under the influence of heat retain their state, but increase their volume very rapidly unless prevented by being confined. In that case they increase in pressure. Solids expand less rapidly than gases.

Expansion through heat may take place in either of three ways, linear, surface or by volume. Of course, the latter includes the other two. Linear expansion is half the surface expansion, and one-third the cubical expansion. There is a definite amount of expansion per degree temperature to all substances. This is known as the co-efficient of expansion. For instance, the co-efficient of expansion of wrought iron is .000006, which means that for each degree Fahr. added, the material will stretch that part of its length. Suppose we have a bar 24 inches long at a temperature of 40 deg., and it is heated to 80 deg. The heat added is 40 deg. The co-efficient for one degree multiplied by 40 gives the co-efficient for 40 degrees. That is $.000006 \times 40 = .00024$. Now this is the fraction of the original length that is added, so we have $.00024 \times 24 = .00576$. This added to the original length gives 24.00576 as the new length. This is true, whether feet, inches, or miles are used as units. A handy rule is when an increase of temperature takes place in a bar to find the new length L, the original length being l, and the increase of temperature t°, and co-efficient of expansion C. $L = l\ (1 +$

ct°). If the bar is acted on by a decrease of temperature, shortening from L to l, then $l = \frac{L}{1+ct°}$

The co-efficients of linear, surface, and volumetric expansion of solids, liquids, and gases, are to be found in tabulated form in most engineering handbooks. Some of the more important metals have the following co-efficients: Wrought iron and steel, .0000065; cast iron, .0000055; brass, .00001. The expansion of steam pipe lines, boiler plates, steel rails, steel bridges, is something which comes under the notice of every engineer daily, and which he must take precautions against in designing and erecting. In some cases this property of expansion and contraction of metals becomes a valuable aid to the engineer, as for instance, in securing crank webs to crank shafts, fly wheels to shafts, and liners to shafts.

Specific Heat

While the subject of specific heat may be followed back to highly scientific investigations, it is not necessary for the engineer who is dealing with practical problems only to go into such refinements. Specific heat, like specific gravity, is used to enable us to compare the various materials to a standard base. Water is the standard for specific gravity, which is to say that 1 cubic foot of water at its greatest density, 39.2 deg., has a weight of 62.425 lbs., usually written 62.5. One cubic foot of cast iron weighs 450 lbs., and, compared to a cubic foot of water, is 7.2 times as heavy, therefore we say its specific gravity is 7.2. One cubic foot of charcoal weighs 27½ lbs., and its specific gravity is .441.

In considering specific heat, we may call it capacity for heat of different bodies. Take again water as a standard, but in this case water at atmospheric pressure and at 62 deg. Fahrenheit. This temperature is taken because the B.t.u. is calculated on the amount of heat required to raise one pound of water one degree from 62 deg. to 63 deg. Now if we want to raise the temperature of a bar of iron, a column of mercury, or a cylinder full of air, it is obvious that they will not each require the same amount of heat. If the bar of iron weighs five pounds and we want to raise its temperature 5 degrees, the amount of heat we must put into it will compare to the amount of heat necessary to raise a like weight of water the same amount, as its specific heat does to 1. The specific heat of iron is .1138. Then we have

$$.1138:1::X:5 = .569$$

As the reader may easily see, the heat required to raise any substance any amount may be found by multiplying its weight by its specific heat and the number of degrees to be raised. For instance, supposing we want to raise 100 pounds of iron 100 degrees in temperature, what number of B.t.u.'s would we need?

$100 \times 100 \times .1138 = 1138$ B.t.u.

The specific heat of water above or below 62 deg. varies from the standard, and this is taken into account in the compilation of steam tables. For instance, water at 212 deg. Fahr. and atmospheric pressure is, according to the scale, just 180 deg. above 32 deg., and would therefore require for one pound 180 B.t.u. However, the heat required is actually 180.531, thus showing that the specific heat is slightly greater than at 62 deg. Fahr. As both temperature and pressure increase, the specific heat rises. Water at a pressure of 300 lbs. per square inch absolute has a temperature of 417.371 deg. That is, it is 385.371 deg. above 32 deg., which is the point always measured from. The quantity of heat required is, however, 390.933, a difference of 5.562 B.t.u. per pound. The temperature of the steam at this pressure is of course the same as the water it is made from . When steam is heated above the temperature corresponding to the pressure, it is said to be superheated, and in this state its specific heat is less than that of water.

As an example of the application of specific heat to practical problems, take the case of different substances at different temperatures mixed together, and it is required to know what the final temperature will be. The most familiar instance, of course, would be that of steam and water. Suppose we have ten pounds of water at 62 deg., and we mix with it 5 pounds of steam at 100 lbs. pressure, what would be the temperature of the resulting mixture?

t = temperature of mixture.
t_1 = temperature of water.
t_2 = temperature of steam.
w_1 = weight of water.
w = weight of water.
s_1 = specific heat of water.
s = specific heat of steam.

Then $t = \frac{w_1 s_1 t_1 + w_2 s_2 t_2}{w_1 s_1 + w_2 s_2} =$

$$\frac{10 \times 1 \times 62 + 5 \times 1.0077 \times 316.893}{10 \times 1 + 5 \times 1.0077}$$

which, worked out, gives 147.4 deg. as the result of the mixture.

Again, suppose we had 100 lbs. lead, 75 lbs. zinc, and 25 lbs. tin, at the melting point and mixed them together, we would get

$$t = \frac{w_1 s_1 t_1 + w_2 s_2 t_2 + w\ s\ t}{w_1 s_1 + w_2 s_2 + w\ s} =$$

$$\frac{100 \times .0314 \times 626 + 75 \times .0956 \times 680 + 25 \times .0562 \times 446}{100 \times .0314 + 75 \times .0956 + 25 \times .0562}$$

$= 486.4$ deg.

In considering the effects of adding heat to gases, we must first explain what is meant by absolute zero of temperature. It has been found that if a cubic foot of gas is raised from 32 deg. Fahr. to 212 deg. Fahr. at constant pressure, it expands to 1.366 cubic feet in volume. That is to say, that in adding 180 degrees to the temperature, the volume has been increased .366. Then, for each degree, the volume increases $\frac{.366}{180}$. That is $\frac{.366}{1000} \div 180$, which, comes to $\frac{1}{491.8}$ or $\frac{1}{492}$ of its volume of 1 deg. temperature. Now this is found to be a uniform addition over the range of temperature taken, and so is assumed to be uniform over any greater range. Supposing instead of the gas being heated it were cooled from 32 deg. downwards. If each degree cooler reduced the volume by $\frac{1}{492}$, when it had been cooled to 492 deg. below zero it would have no volume. Of course, this temperature could not be reached actually, as gases liquefy before reaching so low a temperature, but this assumption is made to enable us to have a definite working point to start from. Supposing we reached this point where there was no volume, obviously there could be no temperature. Therefore, the absolute zero of temperature on the Fahrenheit scale is assumed to lie at a point 492 deg. below freezing point, or 460 deg. below zero.

On the Centigrade scale the absolute zero is at 273 deg. below zero. In theoretical studies of heat, it is the absolute temperature that is used, and it is usually denoted by the capital T.

Expansion of Gases

Gases, in being subjected to heat, differ from solids or fluids in that they possess elasticity and are capable of being compressed. That is, if we take a cubic foot of a gas and enclose it in a cylinder having a weightless and frictionless piston, and apply heat to it, the expansion of the gas will raise the piston. If, now, instead of allowing the piston to rise freely we should place weights on it, the gas cannot expand. In this case, the addition of heat will result in an increase of pressure instead of an increase of volume.

Now this increase of pressure or volume as the case may be is in direct proportion to the absolute temperature.

This may be stated as follows: If a gas is heated while remaining at constant volume, its pressure will increase directly in proportion to its absolute temperature.

If a gas is heated while remaining at constant pressure, its volume will increase directly in proportion to its absolute temperature.

If the gas is cooled the same law applies.

Take a concrete instance as an illustration.

Suppose we have a certain volume of

gas at a temperature of 212 deg. Fehr. and it is heated while remaining at constant volume to 250 deg. Its pressure at 212 deg. is 14.7 lbs. Its absolute temperature is $212 + 460 = 672$. When raised to 250 deg. its absolute temperature is $250 + 460 = 710$. The pressure will be then

$$14.7 \times \frac{710}{672} = 15.5$$

If we have 5 cubic feet at a temperature of 150 deg. and it is raised to 200 deg., the pressure remaining constant, the volume will be

$$5 \times \frac{200+460}{150+460} = 5 \times \frac{660}{610} = 5.405 \text{ cu. ft,}$$

There is a further application of specific heat. When dealing with gases there are two specific heats, one applicable to a gas at constant pressure, and one to a gas at constant volume. These bear a definite relation to each other, and their properties must be understood before the practical study of heat as applied to the steam engine can be examined.

The expansion of gases is governed by two laws, that of Boyle, and that of Charles. Boyle's law states that, "At constant temperature the volume of a gas varies inversely as its pressure."

The law of Charles states that, "Equal increments of temperature give equal increments of volume when pressure remains constant."

These laws are applied to perfect gases, and before proceeding further we will define what is understood by a perfect gas. When work is done on a gas, such as in compressing it, energy is expended. All this energy would appear in the gas as heat if it were a perfect gas. Air is spoken of as a perfect gas, but is not quite so, for at certain pressures a portion of the heat dependent on it does not appear. It is expended on overcoming the friction of the molecules of the air itself, and is absorbed in them. It may be said that no perfect gas has ever been obtained. A perfect gas is sometimes spoken of as a gas that follows Boyle's and Charles' laws.

If a gas is placed in a cylinder, covered with a weightless piston, and heat is applied to it, it will expand. In order to do this, the gas must expend some of the energy divided from the heat applied. Another portion of the heat goes to raise the temperature.

Now, if the same amount of gas is confined in the cylinder and heat supplied to it, but expansion prevented, less heat will be required to raise it to the same temperature as in the first case. This is because the gas is confined, and the molecules cannot lengthen their path when heat is applied to them. The heat that is expended in the first instance in increasing the path of vibration of the molecules of the gas is now conserved. The difference in the two amounts of heat can be defined as the specific heat. If the heat required to raise the temperature of the unexpanding gas is 1, then the heat required to raise the expanding gas will be 1.405. This figure is the one for air, but is very nearly that for several other gases.

To get a proper understanding of the relation of specific heats, and their uses in thermo-dynamical problems, we will follow out the equations of the two laws already mentioned.

Take Boyle's law first: "At constant temperature the volume of a gas varies inversely as its pressure." That is to say, that if we have a volume of gas, say, 2, and a pressure equal to 4, the product of pressure and volume, as long as temperature remains constant, will always be 8, no matter how the pressure and volume may vary. For, if we increase the volume to 4, we decrease the pressure to 2, and if we increase the pressure to 8, the volume decreases to 1. This is expressed mathematically by the term $p\,v = p_1\,v_1 =$ constant. Substituting the figures as above, $4 \times 2 = 2 \times 4 = 8$. The product remains the same.

The law of Charles deals with a gas at constant pressure, the volume and temperature being the varying properties, or a gas at constant volume, the pressure and temperature varying. The amount of variation depends on the absolute temperature.

If a gas at constant pressure, p, is heated so that its volume is increased from v to v_1, the temperature will have increased from T to T_1. The capital T represents, in all cases, absolute temperature. The expression for this condition will be

$$\frac{v_1}{v} = \frac{T_1}{T} \text{ or } v_1\,T = v\,T_1$$

If the gas is kept at constant volume, and temperature added so that the pressure is increased, then the equation is

$$\frac{p_1}{p} = \frac{T_1}{T} \text{ or } p_1\,T = p\,T_1$$

The equation, or we might say the characteristics of a perfect gas, as expressed in an equation, is obtained by combining the equations of Boyle's and Charles' laws. We have seen that gas at a pressure p and volume v, at constant temperature, changed to pressure p_1 and volume v_1, changes its volume in direct proportion to the change in pressure, and we expressed it as

$$p\,v = p_1\,v_1$$

$$\therefore\ p_1 = \frac{p\,v}{v_1}$$

Now, by Charles' law, equal increments of temperature produce equal increments of pressure at constant volume. So, if we have a volume of gas at pressure p_1 which is increased in temperature from T to T_1 and remains at constant volume, increasing in pressure from p_1 to p^1, we have

$$p_1 : p^1 :: T : T_1$$

$$\text{or } p_1 = \frac{p^1\,T}{T_1}$$

The combination of these equations $p_1 = \frac{p\,v}{v_1}$ and $p_1 = \frac{p^1\,T}{T_1}$ gives $\frac{p^1\,T}{T_1} = \frac{p\,v}{v_1}$ and expressing them both in terms of p v by transferring we get

$$\frac{p\,v}{T} = \frac{p^1\,v^1}{T_1}$$

This may probably be made somewhat more clear by taking a numerical example. If we have one pound of a gas, say air, at a pressure of 15 lbs. per sq. in. absolute, and a volume of 12 C. F. and absolute temperature of 520 deg. Fah., this will correspond very closely to air at normal pressure and temperature. Supposing the volume is increased to 18, the temperature remaining constant. Then, by Boyle's law,

$$p\,v = p_1\,v_1$$

$$15 \times 12 = p_1 \times 18$$

$$\frac{15 \times 12}{18} = p_1$$

$$\text{and } p_1 = 10$$

If the volume remains constant at v_1 and the pressure and temperature are increased from p_1 to p^1 and T to T_1 we get

$$\frac{p_1}{p^1} = \frac{T}{T_1} \text{ or } \frac{10}{p^1} = \frac{520}{T_1}$$

Assume that the pressure is increased to 15 lbs., then

$$\frac{10}{15} = \frac{520}{T_1}$$

$$\text{then } T_1\,10 = 520 \times 15$$

$$T_1 = \frac{520 \times 15}{10}$$

$$T_1 = 780$$

$$\text{Now } p_1 = \frac{p\,v}{v_1} \text{ and } p_1 = \frac{p^1\,T}{T_1}$$

$$10 = \frac{15 \times 12}{18} \text{ and } 10 = \frac{15 \times 520}{780}$$

$$\text{so } \frac{p\,v}{T} = \frac{p^1\,v^1}{T^1}$$

Substituting figures

$$\frac{15 \times 12}{520} = \frac{15 \times 18}{780}$$

which, reduced to its lowest fraction, is

$$\frac{9}{26} = \frac{9}{26}$$

or, transposing

$$15 \times 12 \times 780 = 15 \times 18 \times 520$$

$$180 \times 780 = 7800 \times 18$$

$$18 \times 78 = 78 \times 18$$

Now, if T remains constant, p and v alter in inverse proportion to each other. If p and T alter, v remains constant, and if v and T alter, p remains a constant, so the expression

$$\frac{p\,v}{T} = \frac{p^1\,v^1}{T^1}$$

is a constant. So we may denote it by a symbol R and the expression is put

$$\frac{p\,v}{T} = R$$

so that $p\,v = R\,T$ and $p^1 v^1 = R\,T^1$

This is called the equation of the gas. The value of R can be found for any gas, if we know the volume of 1 pound. For instance, air at 14.7 lbs. absolute pressure has a volume of 12.39 C. F. Then $p\,v = R\,T$, and if the temperature is 32 deg. Fahr. or 492 absolute, we have

$$p\,v = R\,T$$
$$14.7 \times 12.39 = R \times 492$$
$$R = \frac{14.7 \times 12.39 \times 144}{492}$$
$$R = 53.43$$

We have been dealing with only one pound of the gas. If we have any larger quantity, say w pounds, then the formula will be $p\,v = w\,R\,T$, or for air

$$p\,v = w \times 53.43 \times T$$

As an example, if we have a cylinder of compressed air containing 10 lbs. air at a temperature of 100 degrees, and a gauge pressure of 100 lbs. per sq. in., what is the volume?

$$p\,v = w\,R\,T$$
$$144 \times 114.7 \times v = 10 \times 53.43 \times 560$$
$$v = \frac{10 \times 53.43 \times 560}{114.7 \times 144}$$
$$v = 18 \text{ C. F.}$$

Do not forget that pressures and temperatures are absolute, and, therefore, 14.7 must be added to gauge pressures and 460 to thermometer temperatures. Also, the pressure per square inch must be multiplied by 144 to bring it to square feet, as we are dealing with volume per cubic foot.

In speaking of a perfect gas, we said that all the heat put in would show as energy. No gas being perfect, some heat is lost in overcoming internal resistance in the gas itself. We therefore can express the action of the heat as applied to a perfect gas by a formula.

If H = total heat
S = heat used in increasing temp.
I = internal work
W = external work

Then $H = S + I + W$.

If the gas were perfect, then I would not appear and $H = S + W$.

From this we see that the heat applied to a perfect gas, which expands against a resistance, will be partially absorbed in doing external work. This heat will no longer be in the gas. The heat remaining will be the difference between the total heat applied and that used for external work, or

if $H = S + W$, then $S = H - W$.

Any alteration in the internal energy of a gas is that induced by a change of temperature, for, if a gas is changed in volume or pressure without the addition or subtraction of temperature, the internal energy remains the same.

The specific heat of a gas at constant volume is denoted by the symbol C v, and at constant pressure by C p. If expressed in foot pounds instead of heat units, the symbols are K p and K v. The specific heat of air at constant pressure is .2375, and at constant volume .1689. Now, multiplying these figures in each case by 778, the equivalent of 1 B.T.U. in foot pounds, we get 184.77 and 131.4. Therefore. C p = .2375 ; C v = .1689 ; K p = 184.77; K v = 131.4.

The specific heats under the two conditions have been determined by careful experiment. The specific heat at constant pressure being .2375, and at constant volume is .1689, then the ratio is:

$$\frac{Cp}{Cv} = \frac{.2375}{.1689} = 1.405$$

Taking the ratio in ft. lbs. instead of heat units we get the same result:

$$\frac{Kp}{Kv} = \frac{184.77}{131.4} = 1.405$$

This specific heat ratio has to be taken into account when considering the action of steam expanding and doing work in a steam engine.

Adiabatic Expansion

Expansion of a gas takes place in one of two ways. If it expands in a closed vessel which is an absolute non-conductor of heat, it will do work without either losing or gaining heat, to the walls of the vessel. Some of the heat will be transformed into work, but none will be lost. This is termed an adiabatic expansion.

Isothermal Expansion

In an isothermal expansion the gas expands at constant temperature, or we may say without loss or gain of temperature. In this expansion the pressure and volume always vary inversely, and $Pv = S$. If we have a cylinder, fitted with a piston, and an indicator is attached, we can move the piston up and down, and if the temperature of the air in the cylinder is kept constant, the pencil will trace a curve, following the same line at every repetition. This curve will be a graphic representation of the variation of pressure and volume, and will be an isothermal curve. The curve obtained by the indicator if the piston were moved rapidly in and out, so that the temperature was raised by the work done on the air, and this heat had no time to be dissipated by radiation, would be steeper than the isothermal. It would be adiabetic. The curve obtained in an actual engine is neither adiabetic nor isothermal but lies between the two.

The Working Cycle

As we have seen in an earlier article, heat and work are mutually interchangeable. This principle is borne out in the steam engine by supplying heat to a working fluid, which changes its heat into work by expanding against a piston, which drives a crankshaft. The heat is supplied by the combustion of fuel under a boiler, evaporating the water and forming steam, which is the working fluid. In the supplying of the heat to the water there is loss due to the inefficiency of the boiler, and from the boiler to the engine there is loss through radiation. In the engine itself there is further loss due to condensation on cylinder walls and passages. A very small portion of the heat contained in the steam is utilized in performing work, the larger part being rejected to the condenser with the exhaust, or to the atmosphere with a non-condensing engine. It will thus be seen how very imperfect as a heat engine, our steam engine really is. The internal combustion engine is much more efficient, the combustion of the fuel taking place in the working cylinder itself. This eliminates a considerable amount of the losses which are encountered by generating steam in a separate vessel. In the internal combustion engine the losses are due to the heat carried away by the jacket circulating water, and that rejected in the exhaust.

In neither of the cases just quoted have we completed the cycle. In a surface condensing steam engine the condensed steam from the engine is returned to the boiler by the fuel pumps. This makes a complete cycle from boiler to engine, engine to condensor, and condensor to boiler. In the engine exhausting to atmosphere and in the internal combustion engine the cycle is not followed through.

A closed cycle is any cycle in which the working fluid returns to its original state. The ideal cycle as described by Carnot is one in which this condition is fulfilled.

In this we have a cylinder, the walls of which are absolute non-conductors, fitted with a non-conducting piston, moving without friction. The bottom of the cylinder is conceived to be a perfect conductor, that is, it offers no resistance to the passage of heat. This cylinder contains one pound of a substance or gas. There is a source of heat, with which the cylinder bottom can be placed in communication, and a refrigerator, or cold body, also capable of being placed in communication with the cylinder bottom.

We will suppose the cylinder bottom to be placed in communication with the source of heat, the gas or substance contained in the cylinder being at the same temperature as the latter. The gas will receive heat and expand, doing work, but the temperature will remain constant. At a certain point the cylinder is removed from the source of heat, and the gas is allowed to expand, doing work, by which a certain amount of heat is changed into work, but none is lost to the cylinder walls or piston, and none is received. The cylinder is now placed in communication with the cold body or refrigerator, and the substance compressed, the heat developed by the work done on the substance being given up to the refrigerator, so that the temperature remains constant. The cylinder is again removed from the refrigerator and the gas is compressed, without receiving or losing heat from any outside source, till its pressure and temperature is again the same as at the starting point. Now, let us follow these four stages out, and see if we can apply the teaching of the previous articles to them.

First, we have an expansion without loss or gain of temperature, which is an isothermal expansion, and follows Boyle's law $p\ v_1 = p_1\ v_1$.

We then have a further expansion in

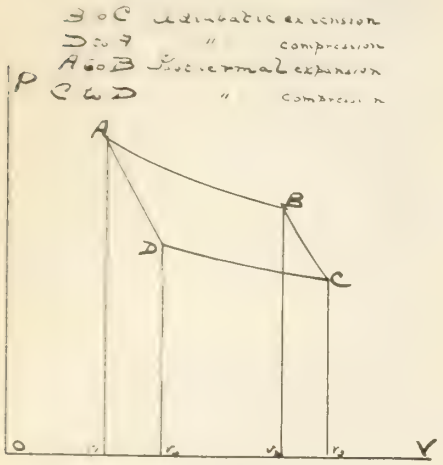


DIAGRAM OF CARNOT CYCLE

which the substance does work, the pressure and temperature drop, but no heat is lost or gained. A certain amount of heat is changed to work, but none is lost, this corresponding to an adiabatic expansion. The equation for an adiabatic expansion must be corrected to take in the ratio of the specific heats of a gas at constant pressure or constant volume.

$$1.405 \qquad 1.405$$

This becomes $pv. \quad = p_1 v_1$

In these two expansions the substance has done work on the piston, and from a temperature corresponding to that of the source of heat, it has dropped to that of the refrigerator or condensor. The piston now does work on the gas, compressing it, the heat of compression passing through the bottom of the cylinder to the condensor, this again being an isothermal compression, as the temperature remains constant. The last stage is compression of the gas to its original point, the heat of compression being retained, raising the temperature to that of the source of heat. This is an adiabatic compression. Now, the heat added to the gas has all been added at constant temperature, and the heat rejected has been rejected at constant temperature. The efficiency of the cycle is governed by the difference between the high absolute temperature and the lowest absolute temperature. This can be expressed by the formula:

$$\frac{T_1 - T}{T} = E.$$

The accompanying diagram shews the Carnot cycle in graphic form. The indicator card obtained from a steam engine resembles this in general form. The isothermal lines, however, are straighter. The action of steam in a steam engine will be discussed in a later article.

"Will say one thing about POWER HOUSE, which is my motto, and that is: If it is not in POWER HOUSE, it is not worth knowing."

W. L. GOODWIN FORECASTS ENORMOUS ELECTRICAL INDUSTRY

THE part Hydro-Electric development is playing in the industrial economy of the Province of Ontario was very strikingly portrayed by the banquet given by the associated electrical organizations in Toronto on Friday, Jan. 16. Over six hundred were present, representative of the following organizations: The Toronto Section of the American Institute of Electrical Engineers, the Association of Municipal Electrical Utilities of Ontario, the Canadian Associated Manufacturers of Electrical Supplies, the Electrical Supply Jobbers' Association, and the Ontario Association of Electrical Contractors and Dealers.

Brig.-Gen. C. H. Mitchell, Dean of the Faculty of Applied Science and Engineering, presided, and with him at the head table were His Honor Lionel H. Clarke, Lieutenant-Governor of Ontario; Sir William Hearst, Mayor T. L. Church, Senator Frederic Nicholls, Prof. A. B. Macallum, K. J. Dunstan, T. A. Russell, P. W. Ellis, Colonel Carmichael, of the Ontario Government; Arthur Hewitt, Major R. W. Leonard, Prof. T. R. Rosebrugh, Col. Alex. Fraser, A. F. Wickson, James White, and Monro Grier, K.C.

Sir William Hearst, in replying to the toast to Canada, said that, looking at the large audience, he now fully realized what electricity meant to Canada. The future of Canada meant the development of its resources. Both the home and the factory were dependent on electricity. Canada was proud of its electrical development and its water powers, and had achieved in the direction of electrical development more than any other country in the world. There was, however, much more left to be done in the development of the white coal. When the ordinary coal and peat were all gone Canada's rivers would all be producing electric power. Referring to the present industrial outlook, Sir William said that everyone looked for a time of depression after the war, but he was glad to say that the output of Canadian factories was only limited at the present time by the amount of raw material they could obtain. He thought the country could look forward to an era of great prosperity in which electricity would play a great part. He contended there was nothing to prevent Canada from a wonderful advancement if the people practised harmony and co-operation.

W. L. Goodwin was the speaker of the evening, and in his address he made a strong appeal for co-operation amongst the varied electrical industries of the province. The electrical industry promised to be a very big thing in the province and publicity would be needed by the industry to drive home to the people all the manifold advantages of electric energy for the home and factory.

There was nothing, however, to be gained by the fighting now going on between public and private interests. There was room enough for both, and both would be needed.

These two branches of the industry, he stated, instead of fighting, should be supporting each other, and should be united in one big campaign to further both their own interests and the interests of the consumer of electrical energy. Plenty of illustrations of the folly of the electrical people engaging in private wars, instead of combining in a big educational campaign which would benefit all, had been furnished in the United States, and this warring of factions, which should be allies, had done much towards retarding the growth of electrical enterprises.

More Power Needed

As Mr. Goodwin viewed it, Ontario is far short of the development she should enjoy electrically. His inquiries had told him that the great bulk of the electricity developed in the province is used in the large centres of population, and even at that, the amount of energy available falls far short of meeting the demands. He appreciated that much of the difficulty was doubtless due to the fact that the demand for electricity had grown during the war, when there were a great many industries engaged in war production, and that since a shortage of power originated during the war, they had never been able to catch up. At the same time, Mr. Goodwin declared that in two years from now, or in ten years, or twenty, or fifty, there will be the same shortage of power, if the various interests insist upon fighting each other. His message, accordingly, was that those engaged in the development of power should look to the future and should plan five or ten years ahead. Particularly did this message apply to the Hydro-Electric Commission, for he pointed out that while the people of different communities may be slow to get the electrical idea, they will be almost insatiable once they get it. The people, as a whole, would have to be educated up to the point of appreciating the value of electrical power, not only for the lighting of their homes and the running of railways, but also for the operation of home conveniences. Going back to the situation in Ontario, Mr. Goodwin repeated that there is still a shortage of power with very little used in the rural districts, and he asked the electrical men present to try to imagine just how great would be the shortage when

the people of the country suddenly became alive to the value of electricity in the home and made their demands. The only possible answer could be greater production.

To the generators of electrical power it might not seem reasonable that they should increase their production when there is not a demand, but Mr. Goodwin declared the experience of the American power companies had taught that it was wise to look ahead; and had taught them that if they looked ahead and educated the public at the same time they would always find that the demand would keep pace with production, if not keep ahead of it. As yet, he added, the electrical industry is only in its infancy, even across the line. He looked forward to the time when all the railways would be electrified, and when that takes place, he declared, it will require more electricity for that use alone than is now used in the whole country. He predicted that the same thing would occur in Ontario, so his appeal to the electrical men was to approach the question not only from the economical standpoint, but also from the standpoint of conserving the nation's supply of fuel. As one simple illustration of the infant state of electricity, Mr. Goodwin stated that electric washers, as home conveniences, should be installed in every household, whereas now they are in less than one per cent. of the homes in the province.

Using Compressed Air for Cleaning Purposes

Explaining How Walls, Ceilings, Windows, Shafting, Electric Motors, Generators, Transformers, Machine Tools, Patterns, Core Boxes, Benches, etc., Can be Quickly Cleaned by Compressed Air

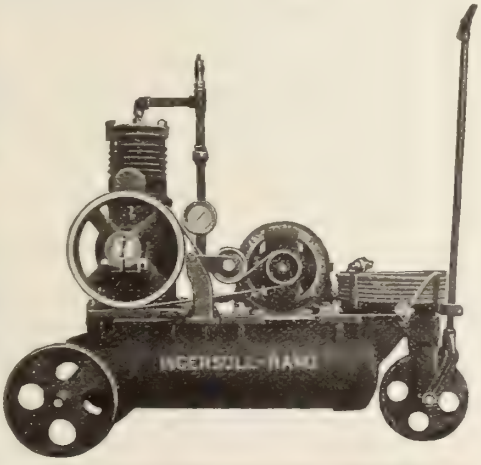
By F. A. McLEAN

THERE are many places in the modern machine shop and industrial plant where compressed air can be appled to considerable advantage for such work as cleaning walls, ceilings, windows, shafting, electric motors, generators, transformers, machine tools, patterns, core boxes work benches etc., as well as for blowing scale from steam hammers, stamping dies, drop presses, etc. One blast of compressed air, properly directed, will instantly clean the cuttings from a bored or drilled hole that would require the expenditure of many minutes' time by the old method of fishing them out with a magnetized file, or a piece of wire, and at the same time the lathe, milling machine, boring mill, or drill press, can be kept entirely free from chips and dirt without the necessity of using a brush or pieces of cotton waste. The equipment is simple and easily installed, and it is usually found that its first cost is quickly absorbed by the reduction in fire hazards and the added convenience and increased efficiency of the plant as a whole.

Most metal working concerns now use electrcity extensively, some operating their own plants, and others using power obtained from central stations or Hydro-electric plants, and it is often found that the motors become clogged up with dust and dirt, causing them to heat up through the reduction of the openings provided by the manufacturer for ventilating purposes, and increasing the liability of burned out coils should they be overloaded at any time, as the additional heat cannot be readily dissipated. Sometimes the motor bearings are oiled too much and the surplus oil gets into the windings, and combines with the dust and dirt to form a mixture whch readily absorbs moisture and shortens the life of the insulation, causing short circuits or grounds to the frame.

While all motors should be cleaned frequently, those installed in foundries and pattern shops, or in places where dust and moisture are always present, should receive more careful attention. Unfortunately, cleaning by hand is often exceedingly difficult, as the ventilation openings are usually too small to admit a brush, and the motors themselves are sometimes located on ceilings or in such cramped places where space in the building is at a premium, that it is almost impossible to get at them without a lot of trouble and inconvenience.

Under such conditions, the air jet has many features which make it of considerable value for this work. In shops where a stationary compressed air power plant is not already in use for operating air hoists, pneumatic tools, sand rammers, etc., a small compressor of the portable, or semi-portable type for belt or electric drive, with a capacity of 3 to 45 cubic feet of free air per minute, at a pressure of 100 pounds per square inch and a receiver holding from 50 to 150 cubic feet, (depending on the amount and frequency of the cleaning to be done), can be purchased at a reasonable price. Where a stationary compressor is already in use it will usually be more convenient to pipe the air about the plant, making suitable openings for hose connections in the various departments where the cleaning is to be done; although in the case of large plants it is sometimes a good plan to use a portable outfit as well. In large plants where there are a considerable number of motors in use, it is a good idea to number them consecutively by means of small brass tags attached to the frames, or by painting the number on the casing. These numbers should then be entered on cards on which a complete record is kept of the date each motor was inspected and cleaned, when it was repaired, and any other information which may seem desirable.

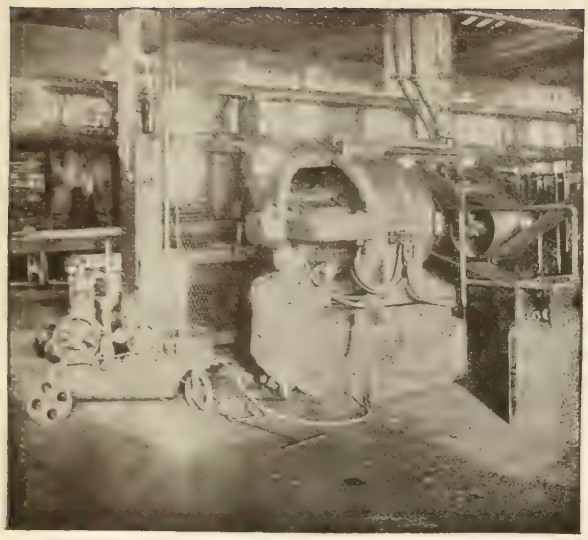


PORTABLE MOTOR-DRIVEN COMPRESSOR OUTFIT.

For blowing out motors and generators, cleaning machine tools, or blowing chips from drilled or bored holes, a nozzle of the blow gun type is the most suitable. The blow gun consists of a solid casting with a metal to metal valve seat, and having no springs, gaskets, or other delicate parts, it is durable, foolproof and not liable to leak. It is shaped in such a way as to lend itself to convenient handling, and the long lever makes it easy to operate, and the short lift ensures prompt closing of the valve when released.

These valves are obtainable with either metal or fibre nozzles of any desired length, the former being suitable for use around machine tools, or general use, while the latter is designed for use on electrical machinery. The principal advantage of this type of valve is, that it does away with the necessity of kinking the hose to stop the flow of air, and operates considerably faster than the ordinary globe valve, with consequent saving in air consumption. In addition to the blow gun it is also possible to buy several styles of self-closing nozzles of more elaborate construction, which work on a somewhat similar principle.

After a motor or generator has been thoroughly blown out it is a good practice to spray the winding with a high grade of air drying varnish, at intervals of six months or a year, depending on



CLEANING A D.C. MOTOR WITH AN AIR JET.

the conditions under which the machine is forced to operate. Before putting on the varnish, which should be applied by a compressed air plant sprayer, it will be found preferable to thoroughly clean the windings with gasoline applied with the paint sprayer, or with a double-barrelled or atomizing nozzle. There are a number of different sizes and styles of paint spraying outfits on the market, and as they can often be used for finishing parts of the product as well as on many other painting jobs around the plant in addition to this work, they usually pay for themselves within a very short time, as the following examples tend to show: From tests made by a large stove manufacturer, it was found that one man with an air brush could paint 100 standard kitchen ranges with air-drying enamel while 30 or 40 were being done by hand. In an electrical equipment factory, a single air brush operator lacquers 3,000 electric light sockets per day, instead of 500 or 600 by hand. With 10 air brushes a maker of brass bedsteads finishes 400 beds daily. An expert hand-painter will enamel from 150 to 200 lamp shades in a day, while, with an air brush, an average workman will turn out from 800 to 1,000 pieces per day.

The outfit illustrated in figure 5 is known as the "Spraco" and has proved very satisfactory in the service of the N.Y.N.H. & H.R.R. for spraying electrical machinery, as well as painting with cold water paints, etc.

The grade and composition of the varnish to be used will depend on whether the motor operates under normal conditions, or is exposed to chemical fumes of either an acid or an alkaline nature. In any case it is best to get in touch with the manufacturer of the motor, giving him an idea of the conditions under which it is used, and then rely on his recommendations in this respect.

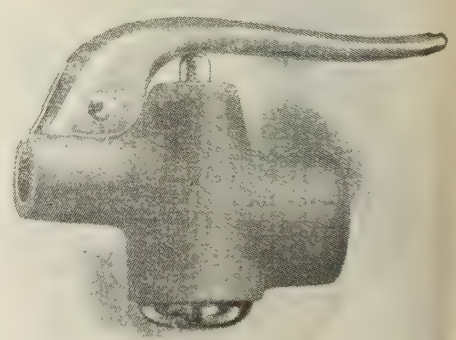
For cleaning motors mounted overhead, ceilings, shaftings, pieces of brass or iron tubing as long as required, may be attached to the blow gun, and since the volume of the air required is not great, the tubing should be of small diameter for ease in handling and economy in air consumption. The end of the tubing may be bent to any desired shape which experience shows to be best suited for a particular purpose. When surfaces of considerable area, such as walls, ceilings, windows, etc, are to be cleaned, a suitable nozzle may be made by bending three or four inches of the tubing at right angles and plugging the open end after a number of small holes have been drilled in the short leg of the ell to form an "air brush." Before using a nozzle of this type, the air pipes should be blown out before attaching the hose in order to prevent dirt or scale in the pipes from clogging the small holes. Nozzles of this style may often be advantageously applied to certain types of annealing and hardening furnace doors, where the men in attendance are exposed to intense heat each time it is necessary to inspect the interior of the furnace. The nozzles are usually placed below the furnace door in such a way that the streams of air rising upward form an air curtain or screen, which effectively protects the operators against the intense heat and prevents the escape of flames each time the door is opened. When used for this purpose the air jet is superior to both water-cooled doors, which only afford protection as long as they are closed, and to exhaust blowers, which subject the workmen to too sudden changes of temperature.

One of the advantages which the air jet has over practically all other methods of cleaning, and which makes it of particular value to a manufacturing concern, is its ability to dislodge dirt and dust while machinery is running, thus keeping the machinery clean, while in no way interfering with its rate of production. While this feature is of considerable value in the metal working plant, it is of even greater importance in some industries, such as textile and paper mills, where the machinery is generally operated 24 hours a day and a few minutes' shutdown every few hours in order to clean the machinery, results in a material reduction in the output per day.

The air pressure required will depend on the nature of the work to be done, 10 to 35 pounds being suitable for blowing light particles or painting motors, etc., while for heavy, oil-laden dust and dirt, pressures of 60 to 100 pounds are more effective. Cleaning is accomplished by the sharp impact of the air upon the material to be removed, and with a suitable pressure this is accomplished as effectively with a small jet as with one of larger diameter. Nothing will be gained by using a large volume of air when a small one will do, as a heavy blast may scatter the dirt instead of merely dislodging it. When cleaning machinery it is advisable to start at the top of the machine and work downward, thus avoiding the necessity of going over any part a second time. It will sometimes be found necessary to instruct the operator how to manipulate the nozzle to the best advantage, so as to avoid blowing the dirt into the bearings of the machine. Should this trouble occur, it may be overcome by employing a lower air pressure. In attaching an air-cleaning nozzle over a machine permanently, care should be taken to suspend it in such a manner that it will not be in the operator's way. It is often possible to hang the hose from a point overhead and toward the rear of the machine, so that it will fall back out of the way when released. The hose should be long enough to reach to the lowest part of the machine to be cleaned, and as it is subjected to considerable wear, it is best to use either the wire wound or armored type, in the 3-8 of an inch size, as this is amply large for most cleaning purposes and is very easily handled.

It sometimes happens that employees who have not been properly instructed, remove the cleaning nozzles, thinking that they will be able to do better cleaning. Others will enlarge the opening in the nozzle by filing, with consequent increase in the air consumption, as may be readily understood by reference to the accompanying table. These troubles may be prevented by placing a reducer in the air supply line, or inserting a hardened steel bushing in the tip of the nozzle. The most effective way of combating these abuses, however, is to instruct the operators carefully and then see that these instructions are carried out.

The air as taken from the ordinary receiver is usually in satisfactory condition for ordinary cleaning purposes. Where some of the older types of compressors are in use, however, oil is used.

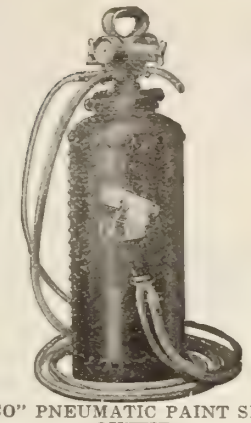


A CLEANING NOZZLE OF THE BLOW GUN TYPE.

too copiously in the air cylinder, resulting in small particles of oil being blown from the nozzle. For ordinary cleaning around the shop this is not objectionable, but for use on fine work, or when cleaning surfaces which are to be painted or varnished, and in textile and paper mills, it is necessary to have the air absolutely free from oil. An oil separator placed in the supply line will remove practically all of this oil, and when it is desirable to thoroughly clean the air, it may be passed through muslin or other light cotton cloths as well.

When cleaning motors before varnishing, and on some other classes of machinery, it is best to use a double-barrelled nozzle, the upper tube of which is connected to the air supply, and the lower by a piece of flexible tubing to a tank containing gasoline, oakite, or some other form of cleaning solution, thus effectively cleaning parts of a machine which could not otherwise be properly cleaned by either method alone.

In factories operating on steam power, compressed air may be readily used for blowing soot and dirt from the boiler flues, etc., for which purpose it will be found much more convenient than steam. The necessity of keeping the heating surfaces of the boiler free from soot is of especial importance when the present high cost of fuel is taken into consideration, as a layer of soot 1-32 of an inch in thickness will reduce the efficiency about 9½ per cent., while, if this accumulation reaches a depth of as much as ¼ inch, the reduction in efficiency will be 80 per cent. or more. When steam is used for cleaning the boilers the water of condensation is usually an objectionable feature, and it is necessary to use heat-proof hose, or insulate the nozzle in some way, so that the operator will have no difficulty in holding it. The ease with which an air hose may be handled, and the absence of moisture in the jet, makes the job much cleaner, and as it facilitates quick work, the men responsible for the care of the boilers feel more inclined to clean them frequently, with consequent increase in the amount of steam produced from each pound of coal consumed.



"SPRACO" PNEUMATIC PAINT SPRAYING OUTFIT.

When at first glance the cost of installing a pneumatic cleaning system may seem unwarranted, this is, however, not the case, as the correct basis for figuring the relative cost and value of the equipment should be the saving that can be effected by its use rather than the actual amount of money involved in its installation and maintenance.

The increase in production which results from the ability to keep the machinery in the plant thoroughly cleaned while it is in operation, will often pay the cost of supplying the air, and at the same time pay a good rate of return on the money invested in the necessary equipment. In many plants where compressed air cleaning systems have been installed, new uses for the equipment have been discovered, which were not thought of at the time the installation was made, and larger outfits have been purchased, as a result of the good service rendered by the smaller units.

TABLE SHOWING FLOW OF AIR.

W. L. ABBOTT JOINS HAYS' SCHOOL OF COMBUSTION

The Hays School of Combustion announces that Mr. W. L. Abbott, Chief Operating Engineer of the Commonwealth Edison Company, Chicago, has associated himself with the Hays Course in Combustion Engineering as Reviewing and Advisory Editor.

Mr. Abbott is widely known for his contributions to engineering literature and his eminent position in the power plant operating field. His co-operation with the Hays School in the training of Combustion Engineers adds weight and authority along practical operating lines to the teachings of the institution and rounds out the faculty, which includes beside Mr. Joseph W. Hays, the author of the course, the following men who are well-known in combustion lines:

Joseph Harrington, Fred R. Low, David Moffat Myers, Professor S. W. Parr, Arthur L. Rice.

The Hays School is fortunate in being able to secure the co-operation of men of such standing without remuneration of any sort. These men recognize the need of training for the cause of fuel conservation and are contributing their services without any charge. This enables the school to distribute the course at a comparatively low cost to the student.

A great interest is being shown in this work and men in every conceivable position related in any way to the use, handling or purchase of fuels, from all parts of the country are enrolling in large numbers. Power plant executives and public utility operating concerns are joining in the effort to advance the cause by making it possible in many cases for their employees to secure training at the expense of the company .

Something For Nothing

IN THESE days of high fuel costs it is no cause for surprise that consumers will carefully study any means of getting better results from the fuel they use. There is plenty of room for legitimate methods of fuel conservation, the efficiency of the average steam plant being of a very low order. Unfortunately, the situation also gives opportunity to the charlatan who is anxious to benefit humanity by a wonderful preparation, which gives heat value by being merely sprinkled on the fuel. The peculiar part of it is that they are able to not only sell the stuff to supposedly hard-headed, though frequently gullible business men, but to get signed statements claiming that the stuff does what it is supposed to. These quacks and their fuel-saving nostrums appear from time to time in different parts of the country. They flourished a brief space and vanish, only to re-appear far from the scene of their former labors.

The basis of all fuels is carbon. The composition of coal is carbon, hydrogen, oxygen, nitrogen and ash. The proportion of carbon varies with different coals, but may be taken as being from 75% to 90% of the total. The heat value of coal, which means the heat available from the combustion of one pound of coal, is anywhere from 9,000 to 14,000 British thermal units, depending on the relative amount of carbon, hydrogen and ash. Oil fuel has a higher heat value than coal, owing to it being without any ash content. It runs as high as 22,000 British thermal units to the pound.

In a recent case we have seen, the vendor of one of these heating compositions claims, by the use of his preparation, to have raised the heat value of the fuel by 50%, and have lowered the ash content of the fuel. Now the ash content of a fuel cannot be lowered. It is there. What may happen is that some ash will fuse at a lower temperature than others, and a higher proportion of unburned carbon may be carried off by it. Providing that the furnace was working at its best efficiency, the only way that heat could be added to the fuel would be by adding some chemical of a tremendously high heat value. Hydrogen has the highest heat value of any chemical, and that is already contained in the coal, and furthermore, could not very well be applied in the form of a solution. Common salt will make a pretty flame when thrown on the fire, but the added heat is nil. In fact, it will probably extract heat in changing its state. There is nothing to back up the claim of added heat value in the case we mention that would receive any consideration from an engineer. If anyone comes to your factory trying to sell a compound that will cut the coal bill in half, insist on him bearing the expense of a properly conducted evaporation test by an independent engineer of recognized ability. If the seller is willing to do this, then enquire into the cost. If anyone buys a cheap compound, or a dear one, for that matter, with the idea he is going to save half his fuel bill, or one-quarter of it, he must be of a highly susceptible nature, and a good subject for a gold-brick artist.

The Future of Electricity

THERE is food for thought in the statement made by U. L. Goodwin, at a recent meeting in Toronto, that it was doubtful if the generation of electricity could keep pace with the demand. Two years from now, or in ten years, or in twenty or fifty, there will still exist the same shortage of power if far-seeing plans are not laid for the future. The time will undoubtedly come when every source of waterpower available at a reasonable cost will be utilized, and that to the utmost.

Reasoning from the above statement it will be possible to predict the changing nature of stationary engineering and to realize how important a knowledge of electrical engineering will be to the stationary engineer.

Steam power will never be entirely superseded, for there is no more economical way of generating power when the exhaust steam can be utilized for heating and other purposes. Many industries throughout the country still retain their steam plants, and many of the newer ones are installing up-to-date equipment of this nature in their power plants, but, in almost all the newer installations of any size the power, no matter how generated, is transmitted by electrical means.

This affects the operating engineer, and it is necessary for him to learn something of the operating characteristics of electrical machinery. He need not know how to design a generator or transformer (only a few in the electrical profession can, it is their job), but he should have a sound grasp of the fundamental principles and should be able to operate and care for the apparatus under his charge intelligently.

His knowledge of this subject should be of a similar nature to that possessed on steam engineering. The designing of a boiler or engine is seldom done by the operating engineer, but no one knows better than he how to operate them.

The Terrific Punch of a Small Boiler

Explosion in Small Shop Where Vulcanizing Was Done Opens Up a Question of Interest—Terrific Power Released Does Great Damage

By T. H. FENNER

IF there are still sceptics on the subject of the dangers of small vessels containing water and steam under pressure and temperature conditions it is surely not through lack of object lessons.

The latest of these demonstrations occurred in Toronto very recently, much to the detriment of the building in which it occurred. Fortunately, or we might say, almost miraculously, it was not accompanied by any loss of life or limb. The case referred to was the explosion of a small cast-iron vessel used for vulcanizing automobile tires, and it was situated on the second floor of a garage and service station on Jarvis Street, Toronto.

The apparatus consists of a cast-iron vessel of square cross-section in the lower part, the upper part being made a semi-circular shape, to conform to the shape of the tire. There are three sections, so that three tires can be handled at once, and the vulcanizing is performed by the heat of steam circulating round the inner surface of the moulds. This steam is generated from the water contained in the lower portion of the apparatus, and the necessary heat is applied by a gas flame on the bottom. The lower part, which is practically a cast-iron boiler, is filled with water through a funnel, and holds probably 50 lbs. of water. After filling, the funnel is removed and the hole plugged. A safety valve set to blow off at about 40 lbs. per square inch, and a steam gauge are fitted.

Where the Valve Stops Work

The pressure used will, of course, never exceed the pressure at which the valve is set, unless something prevents the valve from working. Evidently something of that nature happened in this case, for while the attendant, fortunately for himself, was temporarily absent, an explosion occurred. The result was the complete demolition of the vulcanizer itself, the shattering of every window on the second floor, and the splitting of the front wall of the building from top to bottom.

A very respectable effort for a couple of pails of water, was it not?

As a bystander remarked, one would wonder how such a little thing could do such enormous damage. However, a little study will dispel the wonder, and probably bring home to many more or less complacent users of boilers the nature of the forces they are handling.

We may fill a boiler, or other vessel, with water and then, by means of a pump, produce pressure high enough to rupture the tank. No explosion happens. Why? Because there is no latent energy contained in the water to cause one. The vessel ruptures, and the pressure disappears. The energy contained in the water has been used up in overcoming the resistance of the material to rupture. That is why testing of boilers is always done by means of hydraulic pressure. Water being practically incompressible, a stroke or two of the pump is sufficient to increase the pressure after the vessel is once filled.

But When Heat is Applied!

Now, let us take a vessel, and partially fill it with water, which we proceed to heat, until some of it evaporates, and steam is formed. Instead of the water possessing no latent energy it will possess an enormous amount. To raise one pound of water one degree requires one heat unit, and this heat unit represents the same amount of work as the raising of 778 lbs. one foot high. In other words, the heat unit, known as the British Thermal Unit equals 778 ft. lbs. Now, to change one pound of water at 40 degrees Fahrenheit into one pound of steam at 40 lbs. per square inch gauge pressure requires approximately 1,161 B.T.U's, equivalent to 903,258 ft. lbs., or energy sufficient to raise 1,000 pounds 903 feet high. Now, to come back to our little vulcanizer, which seemed so small as to be harmless. Assuming it held 50 pounds water, and 10% of this had become steam at 40 lbs. per square inch gauge pressure. We would have 5 lbs. steam containing 5,805 B.T.U's. We would have 45 pounds of water at 40 lbs. pressure, the temperature corresponding being 285°F.

Let's See Just What Happens

As the initial temperature of the water is taken at 40°, the quantity of heat in the water would be $45 \times (285-40) = 45 \times 245 = 11,025$ B.T.U. Now, we can neglect the energy lost in breaking the vessel, as we have no means of estimating it, and we will assume that all the energy of the steam and water is available to do its worst to whatever obstructs it. Steam occupies, roughly, 1,600 times the volume of the water from which it is formed at atmospheric pressure. The first thing that happens when the vessel breaks is the reduction of pressure. Now, the water, which is at a temperature of 285° at 40 lbs. pressure, is considerably above the temperature of steam at atmospheric pressure. Therefore, a considerable amount of water will become steam, and will want to increase its volume 1,600 times when it does so. Let us see how much. We have available altogether $5,805 + 11,025 = 16,830$ B.T.U's. Each pound of water in becoming steam at atmospheric pressure will absorb 966 B.T.U's. Therefore, 16,830 divided by 966 will give us the amount of water that becomes steam at atmospheric pressure, roughly, 17½ lbs. One pound of steam at atmospheric pressure contains 1,146 B.T.U's, and 17½ lbs. contains 20,055. All this heat energy is available to remove anything that wishes to prevent the expansion.

See What We Have Now

Translated into foot pounds, the energy is 15,602,790. That is, enough to raise 7,800 tons one foot high, or 1 ton 7,800 feet high. The volume of 17½ lbs. steam at atmospheric pressure is 460.25 cubic feet. That means that in order to occupy that volume that much air had to be displaced, and anything that tried to confine it had to go. Luckily there were plenty of windows, which yielded easily, but not enough, as witness the broken wall. It is no wonder that the place looks as though it had been struck by a shell.

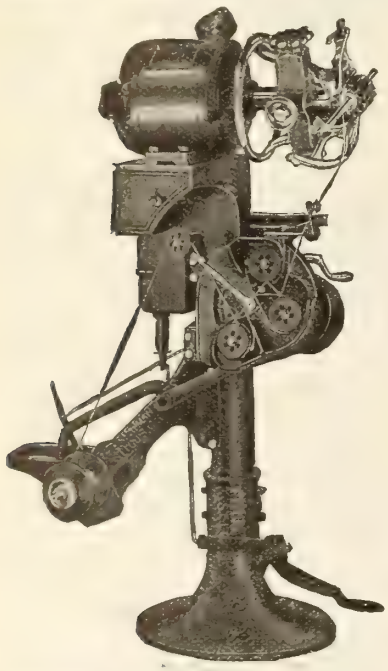
Do not despise the boiler because it is only a small one!

TEN times as much alcohol to be used under prohibition than formerly. This is the prognostication of a member of the American Chemical Society, at a symposium held on the question of alcohol. However, this quantity will not be made up into seductive cocktails, or sympathetic gin rickies. It will be used to propel vehicles, boats, and other power-users when the petroleum supplies become less. There are a number of new sources for the supply of alcohol, one of them being the nippa palm. This palm yields about 15% sugar, which can be fermented. This source alone would give 50,000,000 gallons of alcohol a year.

Progress in New Equipment

NEW ARMATURE WINDER

The P. E. Chapman Electrical Works, of St. Louis, Mo., announces a much more complete model of the Chapman Adjustable Bipolar Drum Armature



GENERAL VIEW OF THE WINDER.

Winding Machine, in their style 3 as shown herewith. This model in addition to being adjustable in a few minutes for any style and size of random wound bipolar drum armatures and any size of wire from No. 20 to No. 36, has some special features enabling it to wind a very great amount of wire into armature slots without pounding the wire, and also has some unique lead forming and handling features reducing the labor on this part of armature winding.

Driving motor, controller, turn counter and other necessary parts are all integral parts of the machine, in fact, the machine is complete in itself.

A new automatic dynamometer controlled real holder and tension device has been perfected, which it is claimed stops all spool troubles and enables quick starting, high speed, great tension and quick stops, so that only about five seconds are required to wind in a coil. This reel holder and tension device are simultaneously adjusted for any sizes of wire by a simple crank, and once adjusted needs no further attention until reel is empty. It is said the announcement of this device has been held back long enough to prove the machine a success in actual practice. In one case an output of nearly 600 per day was obtained where the estimate was 200 to 250. It is claimed that the output of the machines runs into hundreds of armatures per day on many sizes and kinds of armatures; that the saving over hand winding usually is anywhere from 10 to 30 to 1 or even better. It is claimed that the machine is easy to operate, well and strongly built; that it is useful both in the job shop and in the factory. The machine is also useful for winding field coils, smaller armature coils, etc.

ELECTRIC WATER HEATER

The Bridgeport Machine & Tool Mfg. Co., Inc., of Bridgeport, Conn., have recently placed on the market an electric heater which can be used for the heating of water in factories, etc.

This device claims the following features: Clean, sanitary, and sterilized hot water, boiling hot if you desire, instantaneously, then natural cold water through the same faucet. A double valve faucet does not allow the cold water to pass over a red-hot resistance element. The same device will operate on either alternating or direct current.

To install, first remove the ordinary faucet and mount the Geyser. It is equipped to take standard ½-inch pipe. The name plate designates the voltage and amperage, which is all that is necessary to ascertain the proper size wire to be used for connecting direct from the meter to our device.

BRIDGEPORT WATER HEATER

The two voltages supplied are their

110 Volt	60 Amp.
220 Volt	30 Amp.

but they can supply any voltage desired.

COMMISSION OF CONSERVATION, OTTAWA

[Tenth Annual Report]

Students of Canada's resources and of the problems associated with their efficient development will find a serviceable addition to the literature on this subject in the tenth annual report of the Commission of Conservation.

A concise review of the year's work is furnished by Mr. James White, assistant to the chairman. A series of unusually informative contributions includes "Housing, Town Planning and Municipal Government," by Mr. Thos. Adams; "Medicine in War," by Dr. C. A. Hodgetts; discussions of various phases of forest conservation, by Mr. Clyde Leavitt, Dr. C. D. Howe and Mr. Roland D. Craig; and of agricultural investigations, by Mr. F. C. Nunnick. Particularly timely studies of the water-power and fuel situations in Canada are presented by Messrs. Arthur V. White and Leo G. Denis.

This publication will not disappoint the very wide circle of readers to whom it affords an instructive annual resume of problems and progress in respect to the intelligent use and study of our natural resources.

NEW PUBLICATION ON UNDERFEED STOKERS

The "Westinghouse Underfeed Stoker" is the title of a 36-page, 8½ x 11-inch booklet, with an attractive three-color cover, just issued by the Westinghouse Electric & Manufacturing Company.

Under the head of "Details of Construction," it gives a comprehensive description of the leading features of design contributing to the efficiency and reliability of operation. The interconnection of grates and tuyeres and the arrangement of brackets, gears and fuel deflecting plates, are clearly described.

The subjects of "Efficiency" and "Capacity" are taken up together with "Flexibility." Curves setting forth extensive performance data relative to these subjects and others are used to amplify the text.

The Operators' Point of View

GRADED CERTIFICATE CORRESPONDENCE

The Editor:

In your issue of November 20th appeared a letter signed by Chief regarding graded certificates, and a reply to a letter signed Justice. I am opposed to granting certificates in any form to any engineer that is afraid to write on examinations. Chief stated in his letter that Justice was a would-be engineer and a Bolshevik. I am very much surprised to hear Chief express himself in such a manner to a brother engineer. Justice states that some engineers understand engineering from the letter A to the letter Z. Such engineers should not be afraid to write on examinations, and I do not see where graded certificates are going to be of any use to the engineers of Ontario if certificates are going to be granted to men or engineers without writing on same. If such is to be the case, why not give us all firsts and seconds. School teachers and professional men do not get certificates without writing on examinations. Engineers are carrying very responsible positions, where they are responsible for the lives of hundreds of employees. I think very strongly on the same lines as Justice No. 2. If engineers want certificates to hold down the big jobs, let them get down to business and write for their exams., and not try to get them from the Government on the excuse of not being able to figure out the technical points in the graded certificates. As for myself, I have held both hoisting and stationary certificates since 1912 and I feel that I have still a lot to learn about engineering, but I am not afraid to try and get a higher graded certificate than I was able to obtain at first. AN ENGINEER.

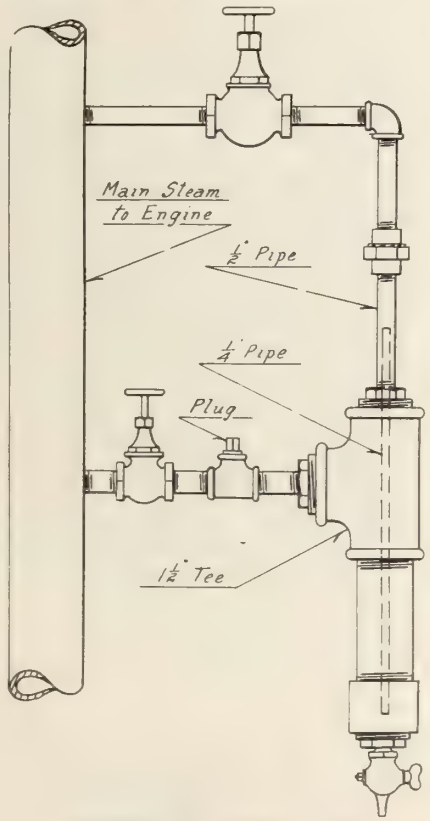
HOME-MADE LUBRICATOR

I see many hints well worth while in "Power House." I am passing along one which you may find to be worth while.

The parts are in most storerooms, and if not, the local hardware usually stocks the fittings. It is the best substitute I have seen for the purchased lubricator.

Half-inch pipe was used, and quarter-inch was forced into the half-inch, after the bushing was on the half-inch pipe to prevent it bursting. The small pipe was made long enough to go up the half-inch pipe a piece, and to reach almost to the bottom of the 1½-in. nipple and coupling. It was not a steam-tight fitting by any means, but it did the job.

The plug in the ½ in. tee is for filling, and if the valves are regulated closely one filling will last two to three hours (the lower valve should be opened first), and water will condense as in up-to-date articles. Any size fittings would do; I used the sizes specified in the sketch.



EXTERIOR OF POWER PLANT

Some time ago I had considerable trouble with packing for a plunger working in coal oil and gasoline. I had some good packing but it was not just the right kind apparently.

An old head told me to get some soap and moisten it until it was soft and slimy, then take candle-wicking or asbestos and draw over the soap until the soap was well worked in. I used this and have had no further trouble. Of course, good packings of all kinds are usually in stock, but sometimes a fellow gets caught. A. O. STONE.

SHOULD VALVES BE SET WITH NO LEAD?

There has been some correspondence in the "Marine Review," of Cleveland, relative to the question of lead on marine engine slide valves.

The first letter published was from Mr. Harry Stone, and appeared originally in "The Bulletin" of the Lake Carriers' Association. Mr. Stone argued that lead on a slide valve was not only of no advantage, but a detriment. He spoke of the result of excessive lead being the pushing back of steam to the boiler by the piston. He also claimed that by eliminating lead a smoother running engine could be obtained, and the revolutions increased. He goes on record as being distinctly opposed to lead, and claims that all text-books which advocate lead, and all teachers who uphold it, are fundamentally wrong.

This letter brought forth a reply from S. H. Hunter, a veteran engineer of the Great Lakes. Mr. Hunter, while agreeing that excessive lead is detrimental, suggests that to get the best results, negative lead, or no lead at top, with ample lead at bottom, is required. He draws attention to the obliquity of the connecting rod affecting the equal distribution of steam at top and bottom ends of the cylinder. He also states that he would like some more reasons from Mr. Stone as to why he is opposed to lead.

Looking over these two letters, it would seem to the writer that both gentlemen had overlooked the fundamental object of lead. Lead is given to a valve primarily to eliminate the wire drawing, which would occur if the valve started to open at the same instant as the piston began its stroke. It must be borne in mind that the piston has travelled a considerable portion of its stroke before the maximum port opening is attained. That is the reason for adopting poppet and Corliss valves in stationary engines. They have the faculty of quick opening, thus tending to keep the admission line on the indicator card a straight line till cut-off takes place. Now, in considering lead of a slide-valve the two gentlemen have evidently neglected the fact that the edge of the valve which governs lead also governs cut-off. Therefore, in raising the valve up so as to obtain negative lead on top, they hasten the cut-off and reduce the maximum port opening. The inside edge of the valve which governs the exhaust has also been raised, and what happens then? Release takes place earlier and compression later. The effect would be in an engine of usual design a very much distorted card, with

a by no means equal steam distribution. As regards the piston pushing the steam back into the boiler, the writer cannot conceive of such a happening. The aim striven for in most engines is to have the compression pressure rise to that of the receiver pressure at the instant the valve opens to admission. This is shown on the indicator card by the compression curve running smoothly into the straight line. As the pressure in the boiler is always appreciably higher than that in the receiver, there can be no pushing back. If we have excessive lead, which also gives late exhaust release and excessive compression, there is a temporary rise of pressure above the receiver pressure, forming a loop at the top of the card. The result of absence of lead would be the very quick drop of the steam admission line from the commencement of the stroke, with a corresponding reduction of area of the indicator card. This means less work and less revolutions.

A certain amount of cushioning is necessary, both to check the inertia of the moving parts and to fill the clearance space with steam. If this is not done, the clearance must be filled with live steam, a dead loss. The functions performed by the steam and exhaust edges of the valves should be differentiated, and excessive compression should not be confused with excessive lead.

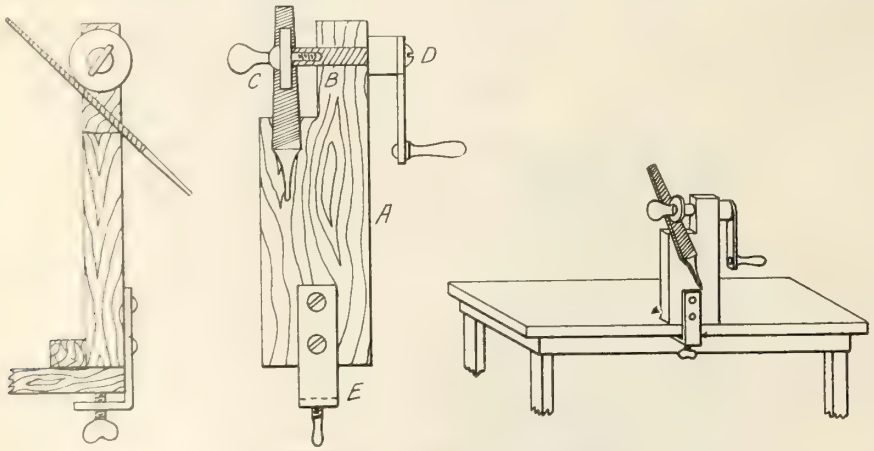
Correspondence on this question will be welcomed.—Editor.

TRIMMING DEVICE FOR WASHERS

The illustration shown is a simple device made from the spindle of a discarded tap for trimming water-tap washers to proper size when they are too large. In many institutions where a great number of taps are in use and of many different sizes, it is quite difficult to have always on hand the exact size to fit them all, making it necessary to trim them down to fit. It is almost an everyday occurrence to renew several washers, and many are made of such hard material that it is very difficult to cut or trim with a knife. They are also a very awkward thing to hold in the fingers to trim and will be a poor job when done. Take a piece of board about 7 in. long, 1 in. thick, 2½ in. wide, cut to the shape shown at A. Bore a hole through the board at the top the size of the spindle with the small end extending ½ in., as shown at B. The washer is fastened to the end of the spindle with a screw to which a small wing handle is soldered, as shown at C. The handle is made of a piece of light flat iron fastened to the other end with a screw, shown at D. The article is fastened with a clamp to a table or bench, or may be fastened to the wash basin or sink if there is nothing else at hand. By holding a file against the washer underneath as shown, and turning the handle, it is quickly and neatly trimmed to the desired size. This little article is not expensive and is easily made, and will be found very useful where there is work of this kind to be done.

J. O. McDONNELL.

Toronto.



TRIMMING DEVICE FOR WASHERS.

1920 CONVENTION OF C.A.S.E.

The 31st Annual Convention of the Canadian Association of Stationary Engineers will be held in Woodstock, June 22, 23 and 24, 1920. In connection with the Convention, the Annual Exhibition of Power Plant Equipment and Supplies will be held.

The industrial development of Ontario has been unprecedented. Numerous new factories are being erected, which will require hundreds of thousands of dollars' worth of equipment, and older factories are extending to adequately take care of new business.

Committees are at work advertising the Convention, and great interest is already being manifested in it.

Any information regarding the Exhibition held in connection with the Convention of Engineers will be cheerfully supplied by the Secretary.

The Editor—It appears to me, when reading the Stationary Engineers' Act, that any employer can hire any man as fireman for six months and at the end of that term discharge No. 1 man and hire another; what advantage has No. 1 fireman in paying five dollars for a certificate, or what is the necessity of it? Information will be gladly received by me through POWER HOUSE.

ENQUIRER.

ENGINEER WINS PLACE ON BOARD OF WATER COMMISSIONERS

The engineer for many years has been content to take a back seat and to let others do the governing of the country. This, needless to say, has been a mistaken inaction on his part and one very much to the detriment of his own interests. The engineer, too, is capable of bringing much of experience and knowledge to bear on the subject of government. municipal or otherwise, and in many cases could replace those of a legal

DAVID L. WEBSTER

turn of mind to advantage.

It is refreshing to note that one city at least in Ontario — Brantford — has now an engineer on the Water Commission.

The many friends of David L. Webster, formerly chief engineer of the waterworks pumping station of the same city, will be glad to learn that he has been successful in contesting the election for this position.

Mr. Webster based his campaign upon the advisability of electing a man who was a trained mechanical engineer, who had years of practical experience, and who knew the waterworks plant thoroughly. It was also contended that a number of costly mistakes had been made in the installation of new equipment and in following the advice of outside engineers not thoroughly acquainted with the system.

D. L. Webster was formerly engineer at the waterworks plant, suceeding his father, the late David Webster, who was for thirty-five years in charge. The son took up a course of study in mechanical engineering at McGill after leaving the public schools and Collegiate in Brantford, later being employed in the machine shop of the Waterous Engine Works. Mr. H. F. Morris secured the contract for the filtering galleries at the Brantford waterworks plant, and engaged Mr. Webster. In 1910 the water commission secured his services, appointing him to succeed his father on the latters' death.

Mr. Webster, since leaving the water-

works system as their engineer, has been engaged in a consulting practice. He is second vice-president of the Canadian Association of Stationary Engineers.

J. H. Williams & Co., makers of Superior Drop-Forgings and Drop-Forged Tools, with works at Brooklyn and Buffalo, N.Y., have just issued a catalog—4x6—106 pages, fully illustrating and describing their standard stock specialties. These include several lines of new goods, viz: "Agrippa" Turning-Tool Holders, Set Screw Pattern, "Agrippa" Boring-Tool Posts, "Vulcan" Forged Cutter Tool Holders and several new assortments or sets of Drop-Forged Wrenches. The book contains, also, a description of the drop-forging process in very simple, non-technical terms for the benefit of those not conversant with its details.

The American Steam Conveyor Corporation, Chicago, announces that the Atlas Machinery and Supply Company are now handling the sale of the American Steam Ash Conveyor in their St. Louis territory. This company has offices at 1416 Syndicate Trust Bldg., St. Louis, Mo., and is a new sales organization in that vicinity.

It is headed by Mr. Wm. H. Patton, who recently returned to the United States after two years' service in the army, during which time he was in nine branches of the service, gaining experience of great practical value.

The Link-Belt Company have issued Book No. 375, dealing with labor-saving elevators and conveyors. Bag pilers of various types are shown together with bag conveyors and telpherage systems. Bale and barrel handling equipment is also described, together with conveyor systems for other forms of containers, such as bottles, rolls, bags, etc. Book No. 380, also just recently issued, deals with electric hoists and overhead cranes. This book is also fully illustrated and descriptive of the use of this class of apparatus in general industry.

BOOK REVIEW

The Coal Consumption of Power Plants and Bonuses for Coal Saving, by Robert H. Parsons. Price 1/- net. The Electrical Review, Ltd., 4 Ludgate Hill, London, E.C. 4.

This monograph of 23 pages, as its name indicates, is devoted to a most important phase of power plant management. It has been written with a view to presenting in handy form the method of establishing and utilizing standards of power plant efficiency devised by the author and used with success. In many large power stations a continuous check upon the efficiency of their operation is now maintained by the method advocated.

The Quigley Furnace Specialties Company, New York, have issued two Bulletins on "Powdered coal flows like water" and "The Quigley powdered fuel system." The former is descriptive of the compressed air transport system used by this firm, while the latter is of a more general nature. Both contain valuable information concerning this type of fuel-burning apparatus.

THE CANADIAN GENERAL ELECTRIC CO.

Have issued Catalogue No. 20 for 1920-21. The matter has been carefully arranged and indexed, and the volume will be found ont of the most complete and reliable guides available on high-grade electrical supplies.

A Real Service to Engineers

IT is good to have come to our ears words of praise from readers of POWER HOUSE, and many such intimations of satisfaction reach us these days. It is pleasing to note the large number of readers who remark that it is not only in the editorial pages but also from the advertising pages that considerable information may be gleaned.

> It is the policy of POWER HOUSE to advocate "efficiency in power plant equipment and service" in the editorial pages, telling "how" and "why" this or that ought to be done, and then through the advertising columns directing attention as to "what" to do it "with."
> The "advertised" way is the better way—because by advertising the chip is placed on the shoulder!

One subscriber told us recently: "POWER HOUSE journal has solved many a problem for me. I wouldn't miss reading POWER HOUSE from cover to cover for the world." More of our engineers and apprentices could very well profit by this tip. Subscribe for and read POWER HOUSE, 'twill make better conditions of mind and ideas for personal development on the job.

Now, we thank all our readers for their good words—to us.

But—we do want you to tell the other fellow, too. It's only by so doing that the real service of POWER HOUSE can be extended.

The subscription price for POWER HOUSE is now two dollars per year. The journal is issued twice a month.

Saves Money—Saves Steam—Saves Time

The Steam Trap Sarco saves money--because it costs but one-third as much as cumbersome float or bucket traps.

It saves steam because it positively does not leak.

And it saves time because it is so easy to install and operate. No supports, building up, pit digging or floor space required. Simply put it at any angle anywhere on the line. It has no complicated system of floats, valves and other parts to get out of order and require constant adjustment.

The Steam Trap Sarco is a simple, compact Steam Trap that does its work efficiently and promptly. It releases condensate as soon as it gathers. Lines are kept drained of all condensate all the time. It requires no storage space. It works on the simple, unfailing thermal principle of expansion and contraction. It has but one moving part and that is practically free from wear.

Made in sizes from 3/8 to 3" for any given pressure up to 200 lbs.

Write today for a Sarco on 30 days' free trial and interesting Booklet "J."

JACKLIFT

—your way to lower labor costs and bigger profits

It can be done—that's why every pulp and paper mill in the United States is using the Jacklift and the platform system for handling pulp and paper. And now the Jacklift is being made in Canada for Canadian Pulp and Paper Manufacturers and other manufacturers who wish to reduce their inside trucking costs.

The Jacklift and platform system in your plant means the easier handling of loads, the quicker movement of materials, less labor, greater economy and less possibility of accidents or damaged materials.

Four Vital Points of the Jacklift

High Lift

A clear lift of 2½ inches by four easy strokes of the handle operating an ordinary jack.

Easy Lift

Four times the handle moving means a lifting ratio of 1 to 35. A girl or boy can easily handle one of these machines with heavy loads.

Angle Lift

The handle will operate at any angle up to 90 degrees as easily as straight away. This, as all of our salesmen know, is impossible with any other truck.

Straight Lift

The Jacklift rises and lowers the load in a straight line—a great convenience, as every other truck operator will tell you.

These four vital points, not contained in any other truck, place the Jacklift in a class away above all competition, and yet the price is practically the same as the other machine.

"New Truths and Old Fallacies" is the title of a booklet just being issued by the Magnolia Metal Company. It discloses an instructive information concerning babbitt metals not generally known or divulged. It is revolutionary in its departure from the generally accepted ideas and practices regarding babbitt metals and users and buyers will doubtless find it a useful guide in selecting such products. Commencing with this issue, and in the first issue each month thereafter, until completed, the content of this booklet will be published serially and in the meantime anyone interested in procuring the booklet, containing the complete article, can do so by applying to the Magnolia Metal Co., 226 St. Ambroise St., Montreal.

PRATT & CADY OPEN NEW BRANCHES

Announcement has just been made by Pratt & Cady Co., Inc., of Hartford, Conn., of the appointment of Mr. E. Coit Magens as director of sales; Mr. O. Lamson Beach, as manager Metropolitan Store, 259 Canal Street, New York City; Mr. Quay T. Stewart, as sales representative, Minneapolis, Minn; Mr. Henry J. Bride, as sales representative, Hartford, Conn.; also the opening of branch stores at 529-531 Arch Street, Philadelphia, Pa., Mr. H. H. Freund, Jr., manager; 505 Mission Street, San Francisco, Cal., Mr. C. R. Mendelson, manager.

In addition to their established lines of renewable disc globe valves, renewable seat gate valves, regrinding swing check valves and asbestos-packed cocks, the company now also manufactures the Davis & Berryman line of feed water heaters, hot water generators and power pumps, having purchased this business from I. B. Davis & Son, the original manufacturers.

In addition, Pratt & Cady have further extended their line by the more recent purchase of a welded steel tubing business and will continue manufacturing welded steel tubing in the various diameters and gauges, and fabricating the same into parts used by manufacturers of bicycles, motorcycles, automobiles, vacuum cleaners, metal bedsteads, etc.

WANTED

Power House Engineer, holding second-class Provincial certificate as assistant to chief engineer, for large industrial plant near Montreal, must be experienced in the operation of D.C. generating sets, transformers, air compressors and hydraulic pumps. Permanent position for the right man. Applicants speaking English and French given preference. State experience, qualifications, age and salary expected. Box 206, Power House.

WANTED

First-class machinery draftsman, by large Canadian in city near Toronto. In making application give details of experience, age and salary desired, etc. Apply Box 205, Power House.

REPORT OF "WILD-LIFE" CONFERENCE

The importance of the wild life of Canada has been recently emphasized by the phenomenal advances of prices at the recent fur sales. High prices have, as might be expected, resulted in an intensified campaign of hunting and trapping of our fur-bearing animals. At present, the market readily absorbs all the furs offered, and the high prices put a premium upon indiscriminate slaughter with the danger of extinction or of depletion of our fur-bearers to the point where recuperation becomes impossible.

In 1913 the Commission of Conservation made a survey of the fur trade, and published a report entitled "Fur-Farming in Canada." In February last the Commission, in conjunction with the Advisory Board on Wild Life, called the first National Conference to consider the large subject of the conservation and protection of wild life. Representatives of the Provincial Governments, the Dominion Government, and sporting and game-protective associations were present. A number of the leaders in this movement from the United States also attended.

The report of this conference has just been issued by the Commission and should be in the hands of not only those interested in the fur trade, but of every lover of wild life. Reliable evidence was adduced of the perils which threaten our fur-bearing animals. The ravages of the "game-hog" are graphically described by Dr. Hornaday, Jack Miner and others.

In contradistinction to the above, it is a pleasure to read of the results obtained by Mr. Jack Miner and Miss Edith Marsh in protecting wild birds in sanctuaries on their respective properties.

Regulation of the fur trade and methods for the collecting of fur statistics are interestingly dealt with, and the organization of local game protection associations is strongly recommended.

The report explains the scope of the Migratory Bird Treaty, the measures taken to enforce its provisions, and other appurtenant data with which the sportsman should be familiar.

The Commission of Conservation is endeavoring to interest the public in wild life protection. The publication of the report of this conference and subsequent conferences will give the necessary stimulus to this important work.

New Coal Operators' Association.—The coal operators in Alberta have split their organization, and a new one has been formed called the Red Deer Valley Coal Operators' Association. Out of 42 members in the original association, 19 resigned, among them being W. R. Wilson, the president. His place has been taken by O. E. S. Whiteman, manager of the International Coal & Coke Company, Coleman, Alta.

FIREBRICK WORK

Boiler Settings Built to Last

We are commonly known amongst the trade as "SAFETY-FIRST SEXTON." Why?—because we take extreme care with our work down to the last detail. Firebrick work is our specialty and when we complete a job it can be relied upon.

HEAVY DUTY MOTORS

with guaranteed overload capacity!

Through thirty years of constant effort Sturtevant direct-current electric motors and generators have been developed to an enviable degree of refinement and excellence. They range in size from the fractional horse-power motor to the generators of 600 KW capacity. All types are of simple, compact, and efficient design, and intended for constant full-load operation with guaranteed overload capacity. The skilled workmanship and selected materials employed in the rugged construction are assurance of enduring reliability and power economy. They can be used with equal efficiency for group, as well as individual drives, such as fans, air compressors, pumps, machine tools, etc. Made to standard voltages, although special speeds and powers have also been developed. Built open, semi-enclosed, or fully enclosed, as conditions require. All standard types are kept constantly in stock and can be shipped immediately. Write for our new Catalog No. 264U.

They Stay Right

When the power house superintendent makes an inspection of the pipe lines he tests the valve bearing the Jenkins Bros. Diamond trade mark with a smile of confidence. He knows from experience, that above all things it can be depended upon to STAY TIGHT. Only valves of highly scientific design and quality construction can be depended upon to stay tight under severe conditions – Jenkins Bros. Valves are made of first-class material by workmen who know Valve requirements.

Furnished in brass or iron body, in globe, angle, cross, check, Y or blow-off, hose whistle and other patterns.

DEPARTMENT OF LABOUR

Ontario Government

Minister:
Hon. W. R. Rollo.

Deputy Minister:
W. A. Riddell, Ph.D.

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a STATIONARY steam plant of 50 B.H.P. or over, in the Province of Ontario, must hold a Stationary Engineer's certificate from the Board of Stationary & Hoisting Engineers. Anyone operating such a plant without a certificate is liable to the penalties set forth in the Act respecting Stationary and Hoisting Engineers.

After January 1st, 1920, the Certificate issued by the Board will be of four grades, viz., First, Second, Third, and Fourth. Application forms for graded certificates will be mailed upon request after the above-mentioned date. The certificates now issued by the Board will be graded into Third and Second-Class upon renewal, same being classified from the information contained in the renewal application which will be sent to each certificate holder.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse-power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a certificate is liable to the penalties set forth in the Act respecting Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1st, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request. The B.H.P. and other information contained in these forms is to be used for statistical purposes. A Registration Certificate will be issued to each applicant. All applications, or requests for same, should be mailed to the Chairman.

W. C. MCGHIE, CHAIRMAN OF BOARD

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., c. 61.

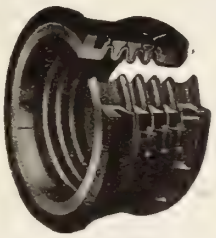
Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, Parliament Buildings, Toronto.

D. M. MEDCALF, CHIEF INSPECTOR OF STEAM BOILERS

BADGER
SELF-EQUALIZING EXPANSION JOINTS

Corrugations on Joints 6 inches and over are 2¼ inches deep



On Joints under 6 inches the corrugations are 1⅛ inches in depth

Perfect Stress Distribution under all Pressures and no cracking or jamming or Pipe Distortion whatsoever

ACT NOW!

You will be safe-guarded against boiler explosion due to low water, if you use VIGILANT REGULATORS. They cannot fail to operate and keep the water level where it will enable the boiler to produce the dryest steam at the highest economy figures.

The slow uniform feeding of these regulators means fuel economy because the feed water is then heated uniformly to a higher degree.

Our instructive catalog will tell you more about the reason why the Vigilant will accomplish all that we claim for it, and more. Write.

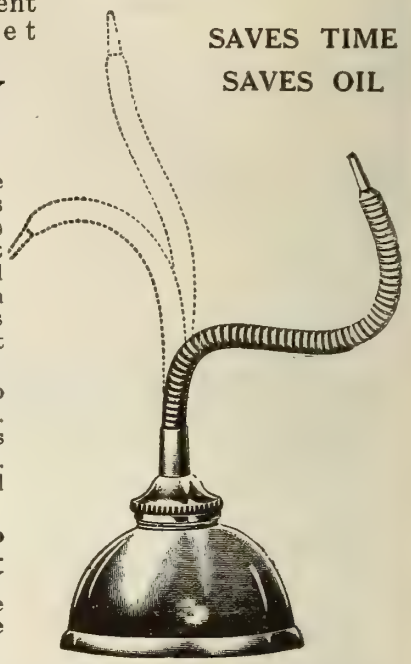
"SAFETY FIRST"

Bend the Spout
to suit position

Every requirement satisfactorily met with

ALL-WAY OILERS

SAVES TIME
SAVES OIL



Note the flexible spout. It enables you to oil all places —many places that previously could only be reached with force pump cans with specially bent spouts.

Indispensable to those who know. Will last as long as six ordinary oil cans. Saves 50% of oil bills.

Ask your dealer to show you the complete ALL-WAY line of oilers. If he cannot do so, please write to us.

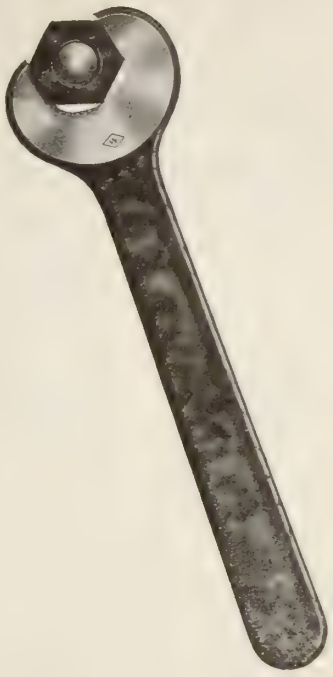
—for every purpose



WILLIAMS' Superior Drop-Forged Wrenches are made in nearly one thousand sizes with openings from 3/16 to 7⅝ inches (4.8 to 194 mm.)—"a Wrench for every purpose." And every one is the product of drop-forgers with nearly half a century's experience behind them. That's why *good mechanics* invariably prefer Williams' Wrenches.

Williams' Drop-Forged Wrenches

What a Canadian Advertiser Says:

The following letter, by no means an exceptional one, accompanied a renewal advertising order received on January 10th, 1920. Such expressions emphasize the fact that our policy of "Efficiency in Power Plant Equipment and Service" is accomplishing splendid results for readers and advertisers.

"Gentlemen:—

"Enclosed please find our contract for space in 'Power House' for the coming year.

"I wish at this time to express my very high opinion of the value of your paper, both from an editorial and advertising standpoint. As a matter of fact, after many years' experience in space-buying, I have reached the conclusion that the value of space in a paper is of value to the advertiser in direct proportion to the value of the editorial matter to the reader. You certainly have a very capable editorial force, and we want to compliment you upon this feature of your paper as well as to express our thorough appreciation and satisfaction with the results secured through our advertisements."

Are You a Reader of "Power House"?

The subscription price is $2.00 per year for 24 books, brimful of choice, up-to-date information.

Are You an Advertiser in "Power House"?

Full information and rates supplied quickly on application. A.B.C. Audit of Circulation.

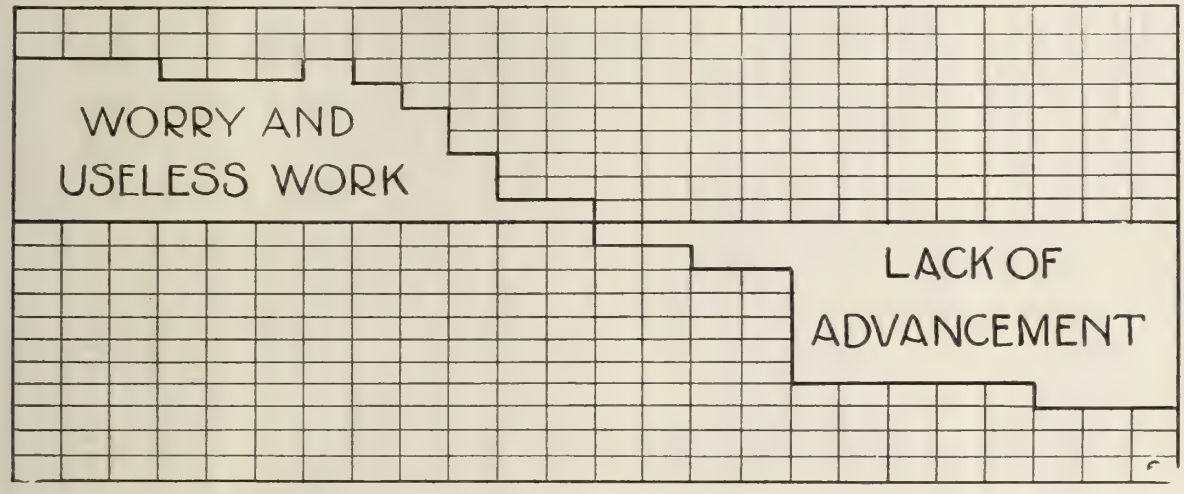
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

PLIBRICO

A High Grade Refractory for Furnace Linings

BETTER THAN FIRE BRICK

1. It's Jointless.
2. It's Plastic.
3. It's air and gas tight.
4. It will stand 3100° F.
5. It will save fuel.
6. It can be installed by inexperienced labor.
7. It will outlast fire brick.
8. It can be used in any boiler, furnace or oven.
9. It can be used wherever fire brick is used.
10. It can not be excelled for patching broken and burned out linings.

Any Engineer can see the economy and advantage over Fire Brick

Are You Able to Turn Your Spare Hours Into Dollars?

If not—and you are really trying to cash in on the spare moments you have during the day or after working hours—if you have made up your mind to take hold of some proposition and sail right in and actually increase your monthly income without hindering your regular work—surely you will want to know about MACLEAN'S plan for making each spare moment count. And even if you are already making money during your spare time—still you can add to your income with very little additional efforts. For you can have full particulars of MACLEAN'S plan absolutely free. If you will merely drop us a card we will send you the complete details of this plan. It will cost you nothing to find out exactly how others with spare time have materially increased their monthly earnings. For full information or the agency in your locality, write and right now,

Over 18 gage	102	252			

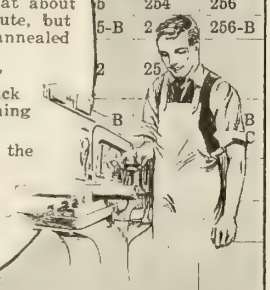
Get the S. P. M. Right

Don't run blades too fast in power machines. You can cut soft steel, if you use compound, at about 100 strokes per minute, but don't try it on unannealed tool steel.

"Haste makes waste" just as much in hack sawing as in anything else.

Send for a copy of the Starrett Catalog No. 21 "CD" and Chart "CD"

42-983.



Numbers above are those given in the Starrett General Catalog and on boxes containing the blades

POWER HOUSE

A semi-monthly newspaper devoted to the Generation, Transmission, and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Published by The MacLean Publishing Company, Limited, 143-153 University Ave., Toronto

MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1103 Union Trust Bldg.

Vol. XIII.—No. 3. Publication Office, Toronto—February 5, 1920 Published Semi-Monthly Canada, $2; U.S. $2.50 a year

Sketch above represents the fire box of a water tube boiler lined with PYRO-PUTTY.

PYRO-PUTTY TRADE MARK REG. U.S. PAT. OFF.

FIRE BRICK IN PUTTY FORM

will minimize your boiler furnace troubles and expense—*and save you fuel*

Pyro Putty is far more durable than standard fire bricks for making new furnace linings, because it is not weakened by a multiplicity of fire clay joints.

PYRO-PUTTY is put up in 700-lb. barrels in a stiff, moist, pliable, "ready to use" condition.

PYRO-PUTTY will prove economical for repairing worn fire brick furnace linings, because repairs can be made quickly by unskilled labor.

May we send further information and prices?

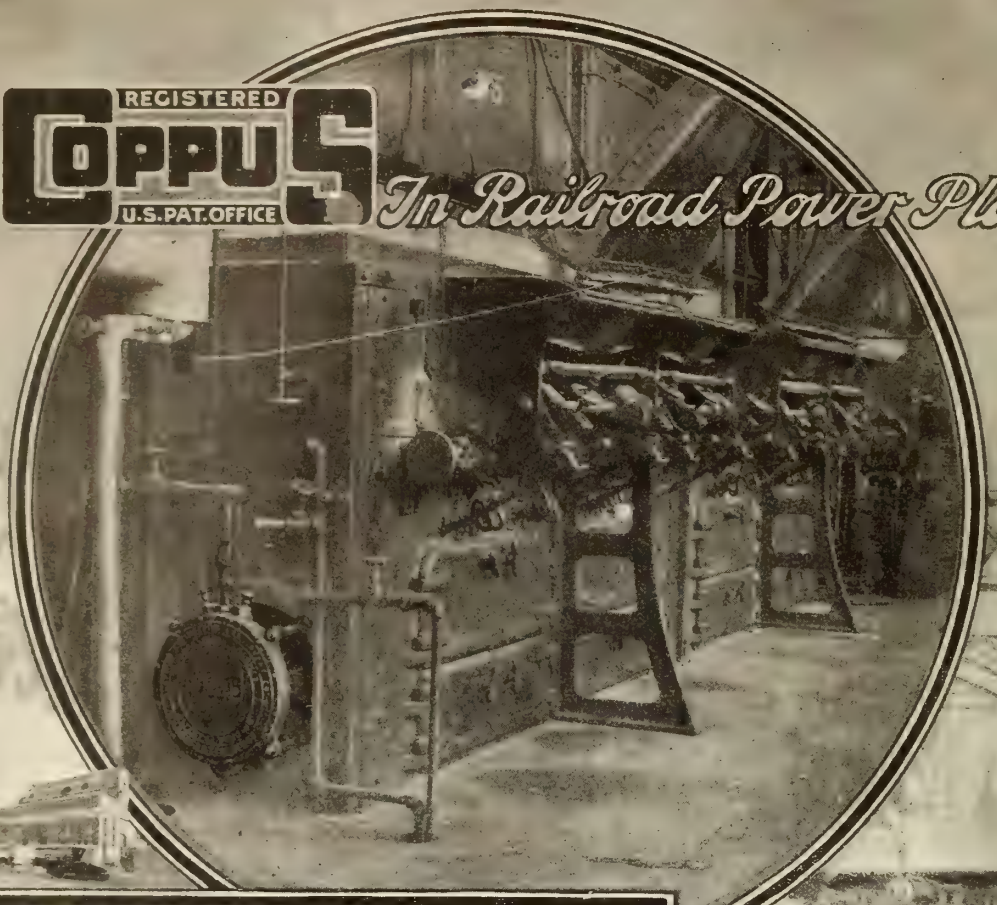
"A few barrels of Pyro-Putty should be part of the emergency equipment of every steam power plant."

PYRO PRODUCTS COMPANY

P.O. Box 685, Toronto, Ontario

REGISTERED COPPUS U.S.PAT.OFFICE

In Railroad Power Plants



Railroads are sticklers for efficiency. Equipment approved by them must produce results — save money — earn dividends. The fact that the Central Railroad of New Jersey operates twenty-six COPPUS Turbo Blowers in their great shops at Jersey City —proves that these blowers **pay.**

Every one of this big battery of blowers—one of which is shown above—has cut coal costs—reduced labor charges—and saved dollars. In this power plant—as in thousands of others—COPPUS Blowers keep up steady steam pressure—prevent clinkering—meet peek loads quickly—and burn cheap fuel. COPPUS Blowers **pay a profit** to the Central Railroad of New Jersey. **They can do as much for you.** Why not put them on the job? Catalog H-23 will show you how

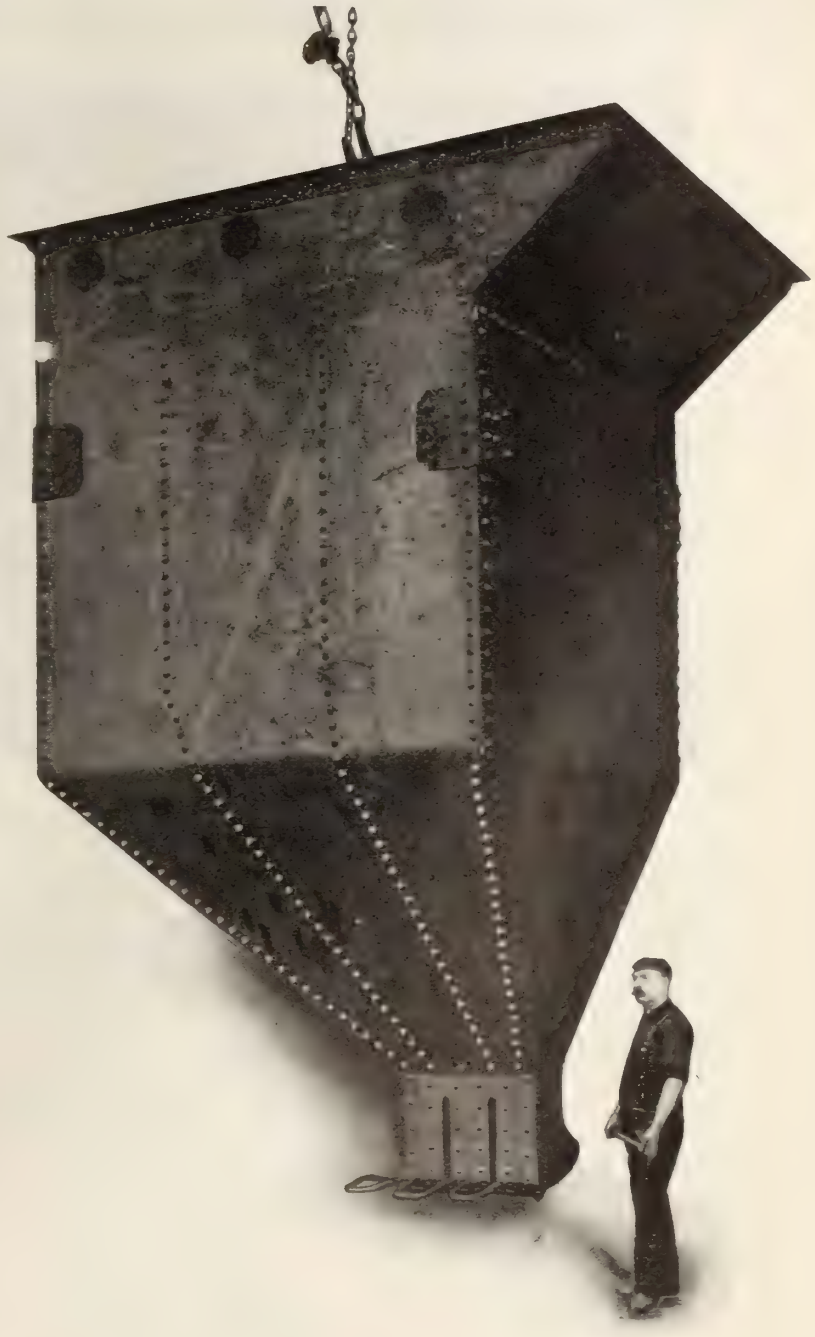
STEEL TANKS AND BINS

We have made a success of building steel plate work by specializing in it.

The new additions and improvements to our boiler shops have placed us in a better position than ever before to do this work right.

Our facilities in every department have materially increased. We have the equipment and the experience to turn out this special work as it should be.

If you are confronted with any problem on this work, send it in and let our Engineers give you the value of their experience.



We design and build:

CONVEYORS
SMOKE BREECHINGS
STEEL STACKS
SPARK ARRESTORS
STEEL BUCKETS
ELEVATORS
RIVETED TANKS
STEEL TANKS
STORAGE BINS
COOKERS AND DIGESTORS
STEEL GAS MAINS

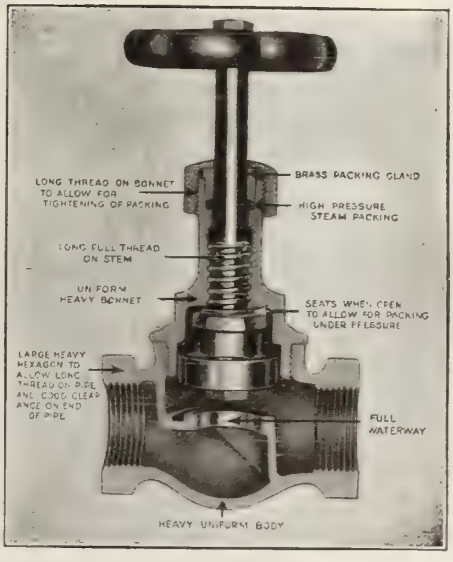
211 BOARD OF TRADE BLDG. - - MONTREAL

"The Valve O'Nine Points"

There are nine outstanding features of the "EMCO" Composition Disc Valve—plainly shown in the accompanying illustration—which in themselves are sufficient reasons why this valve is superior to any other.



LONG THREAD ON BONNET TO ALLOW FOR TIGHTENING OF PACKING
BRASS PACKING GLAND
HIGH PRESSURE STEAM PACKING
LONG FULL THREAD ON STEM
UNIFORM HEAVY BONNET
SEATS WHEN OPEN TO ALLOW FOR PACKING UNDER PRESSURE
LARGE HEAVY HEXAGON TO ALLOW LONG THREAD OF PIPE AND GOOD CLEARANCE ON END OF PIPE
FULL WATERWAY
HEAVY UNIFORM BODY

Cross Section
"Emco" A840 Composition
Disc Valve

Combined with these

there is superiority of strength, durability and workmanship which is the outstanding quality of every "EMCO" product.

Registered in the following Provinces as follows:—

Globe Valve A840	
British Columbia - -	No. 2590
Alberta - - - -	No. 1102
Saskatchewan - - -	No. 2365
Ontario - - - -	No. 1755

The design is approved and registered in the Provinces of the Dominion by inspectors of steam boilers for a pressure of 175 pounds.

Made of the best bronze metal, each valve is subjected to a thorough hydraulic test before it leaves the factory.

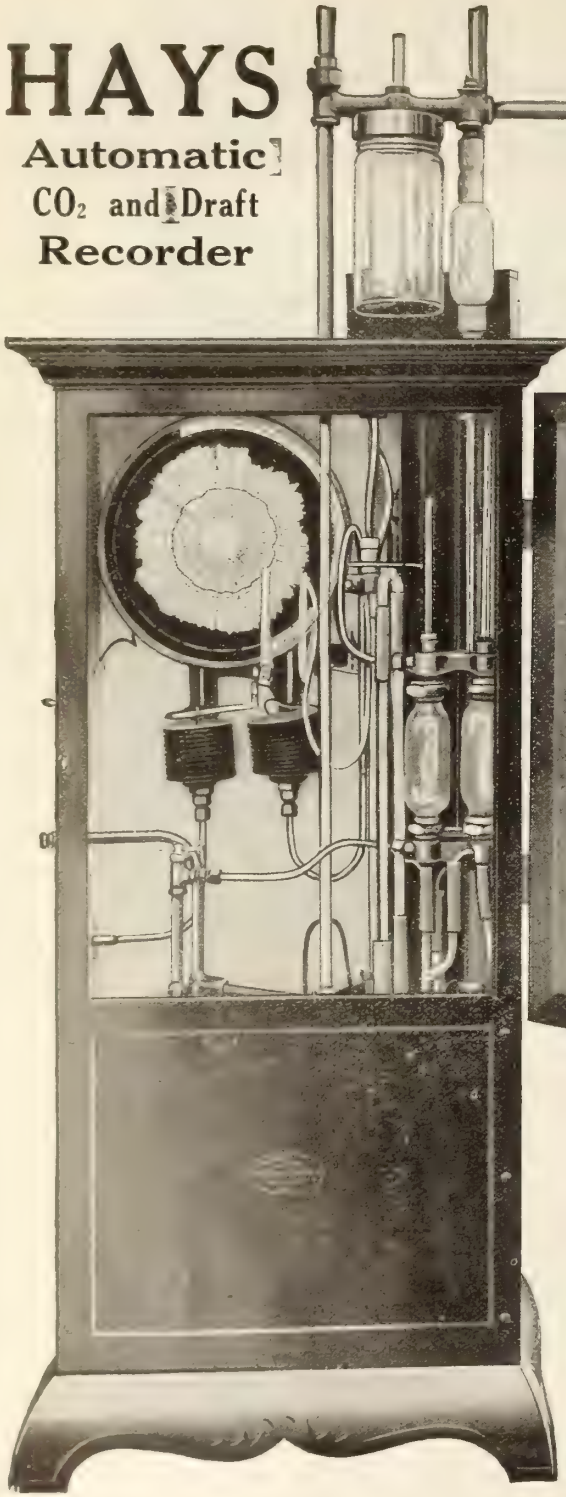
We can make prompt deliveries. Write for prices, etc.

Empire Manufacturing Co., Limited

London and Toronto, Canada

HAYS
Automatic CO_2 and Draft Recorder

Reduces Fuel Expenses 25%



The Hays Automatic CO_2 and Draft Recorder gives a constant gas analysis and a continual record of draft conditions. The slightest error in firing can be detected and corrected. The CO_2 Recorder will spur your firemen to greater efforts and thereby save money for you.

Install a Hays Automatic CO_2 and Draft Recorder and you will automatically bring to your plant the *Economy* of sustained efficiency. The Hays Draft Gauge is the fireman's best friend; it helps him produce maximum steam pressure with minimum amount of coal—Fuel Expenses are reduced 25%.

With the Hays Automatic CO_2 and Draft Recorder the ordinary fireman may become an expert flue gas analyst and reach the standard of efficiency in the combustion of fuel without the knowledge of what the atomic weight of carbon may be, or why one atom of carbon unites with two of oxygen to form the gas CO_2.

Any man who can read a thermometer, who is able to give the temperature of the boiler room, is qualified to bring any boiler furnace to the highest standard of efficiency with the Hays Automatic CO_2 and Draft Recorder.

We manufacture Draft Gauges for all makes of furnaces.

Write for complete literature covering our full line of combustion efficiency appliances.

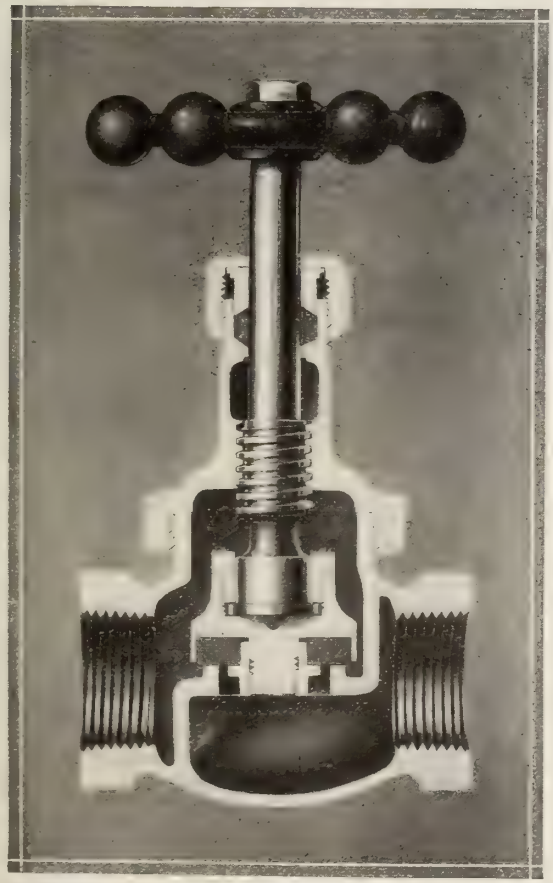
TRADE
PENBERTHY
MARK.

BE SURE THIS NAME is on the Valve you buy



SECTIONAL VIEW OF PENBERTHY COMPODISK VALVE
Registered and Approved for 175-lbs. Steam Pressure

Then you get "The valve with the outside bonnet construction."

The first progressive improvement made in brass valve construction in generations.

Think of the advantages! Valve always accessible.

No straining or stripping of threads when assembling or taking apart.

Impossible to spread or enlarge body of valve when screwing down bonnet to place.

No corrosion of threads, for they are on the outside, away from the action of steam and water.

How to measure the cost of a gasket

WHY should the cost of a gasket be measured by the actual cost of the piece of sheet packing from which it can be cut? If a gasket blows out, its cost will certainly be many times the difference between the price of a poor packing and that of good packing at a few cents more per pound.

Do you realize that a 4 in. flange can be **properly** gasketed at an **additional** expense not exceeding 2 cents even if the proper sheet packing costs 20 cents per pound more than the ordinary kind? You would not be willing to have a gasket blow out for 2 cents or many times 2 cents.

Even where a small difference in price per gasket might amount to a considerable total, remember this—the risk of blow-outs increases directly as the number of gaskets.

Service Sheet, from which gaskets are cut, is the result of the elimination of weaknesses in sheet packing. Service Sheet may cost more per pound—and even more per gasket than some other asbestos fibre sheet packing—but its factor of safety is figured so high that the possibility of a blow-out is, as nearly as possible, eliminated. There's a better way of figuring the cost of a gasket, rather than by the cost per pound of the sheet from which it is cut.

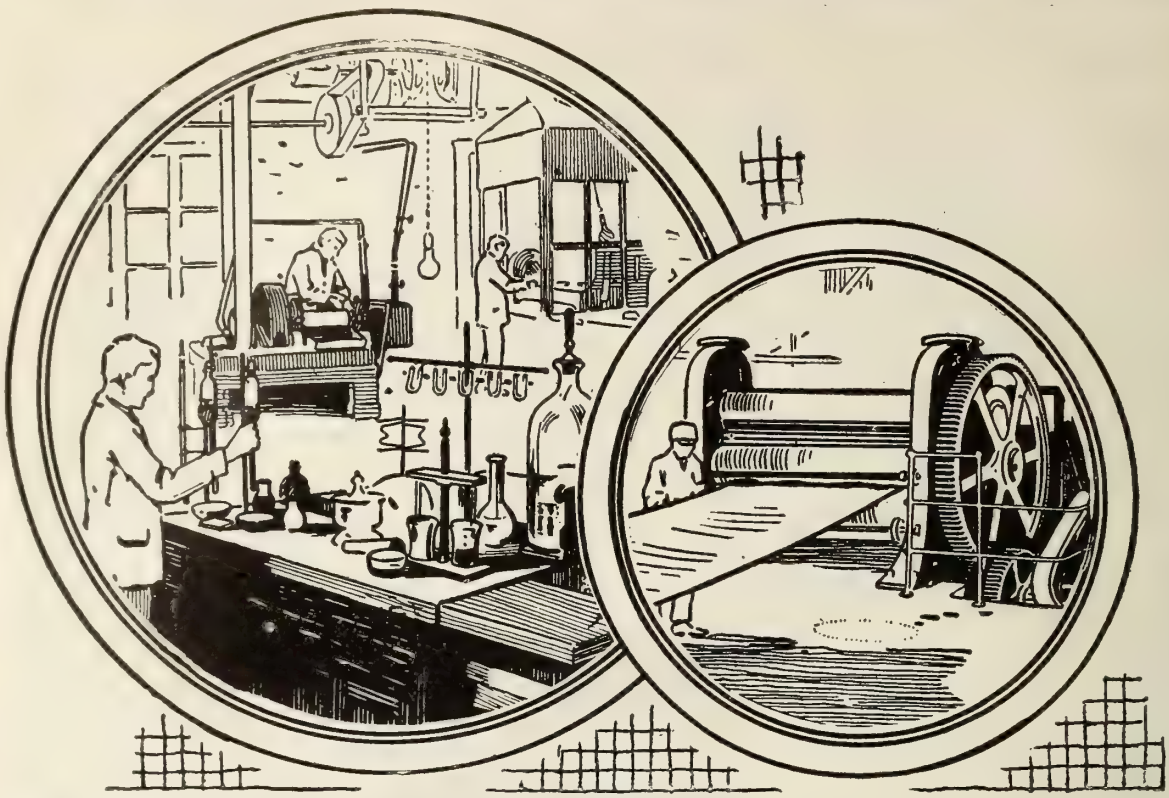
POWER PLANT MATERIALS



The Quality Standard That Produces "Plus Service" Belting

The only sure way to get satisfactory service is to buy products of known worth.

In Dominion Rubber System Belting, the worth is known because every ounce of material—each individual operation and each finished belt must test up to the highest quality standard ever made for belting.

From the time the materials come into our factory until the belt is running on your pulleys, there is no chance of your getting anything but "plus service" belting.

This is the result of over fifty years of belt making experience and research by the oldest, largest and most completely equipped rubber organization in Canada.

The rubber that goes into Dominion Friction Surfacing Belting is not a mere waterproofing substance—our chemists have given it a far greater value by making it into a friction compound that prevents practically all power wastage on the pulleys.

"Plus service" includes the free technical advice of our belting engineers who are ready to help you with your transmission and conveying problems without placing you under obligation to us.

A phone call, wire or letter to our nearest branch places all of our facilities at your disposal.

DESCRIPTION

1. Square packing ring forced against leaky joint.
2. Inside ring forced against packing 1 by screws 4.
3. Outside ring, bolted around by large centre bolt, secured by set screws 5, prevents slipping when adjusting screws 4.

Keep one on hand for emergencies

You never can tell when a joint in some important pipe line will spring a leak, causing danger, loss of power and perhaps a shut-down of the plant. But these troubles can be averted by having on hand some Yarway (formerly the Simplex) Pipe-Joint Clamps ready to meet the emergency when it arrives.

Why take a chance? Provide yourself at the earliest moment with sizes to fit each line. It's the cheapest insurance you can buy.

Thousands in use.

You can try one for 30 days subject to return. Write to-day.

LINDE

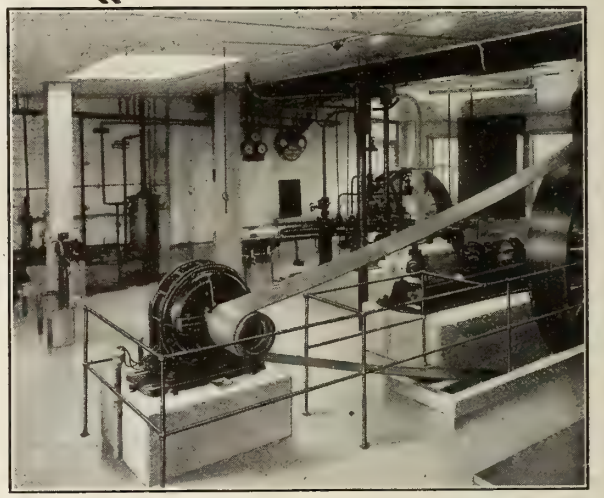
Sets the Standard for

ICE-MAKING MACHINERY

FOR EVERY PURPOSE

Economical - Efficient

100 ton Linde Refrigerating Plant in Operation.



Is your refrigerating system thoroughly efficient? If not it will pay you to install LINDE equipment. We can meet all requirements. Our new vertical enclosed type machines are suitable for plants from 1 to 30 tons. Then for heavy demands, calling for loads up to 300 tons, our horizontal frame type is guaranteed to give better service than any other refrigerating equipment on the market.

By adopting Linde equipment in the place of old and insanitary methods you increase your profits. Write to-day for information.

Tighter Joints and Lower Installation Cost

In addition to its high heat-insulating efficiency, its demonstrated durability and its fire-retarding properties, Nonpareil Corkboard also offers definite advantages from the standpoint of economical installation.

Every carpenter knows that in the erection of a building, the use of well-cut lumber saves both time and labor. And the same thing is true of corkboard. Sheets which vary in size and whose edges and ends are not square, are harder to install than those of uniform dimensions.

The ends, sides and edges of each sheet of Nonpareil Corkboard are trimmed by accurate machinery. As a result, all are exactly alike—uniformity of size is assured. This one feature provides two important things: Low cost of installation and joints that are tight.

Even though Nonpareil Corkboard is a little higher in price than some competing materials, a comparison of qualities will show clearly the reason for the difference.

If you want to know about ALL of the advantages of Nonpareil Corkboard, read the 152-page illustrated book, "Nonpareil Corkboard Insulation." Just write and tell us that you would like to have a copy and we will send one free of charge.

EXTRA POWER BELTING

Pulling the Peak Load

Nearly every industry has some belt-drives with variable loads.

Nearly every industry has had belt trouble when the peak came on these drives.

One of the best things Goodyear Extra Power Belting does is to take care of peak loads without trouble.

How it has solved one peak load problem is told in a letter to us from the Chisholm Milling Company (reprinted here).

The very qualities which give Goodyear Extra Power its great advantage where loads vary, make it a better belt for all-round use.

The *pulley-gripping friction surface* pulls over the stiff places and prevents power waste through slippage.

The *great strength of the fabric plies* which are welded into one by much fine rubber, gives very long life.

Practically *all the stretch is taken out* of Goodyear Extra Power before you buy it—saving costly shut-downs to tighten belts.

The fine rubber, *which seals the seam*, prevents ply separation.

Over 1000 Canadian industrials have found Extra Power Belting an economical proposition—in price, in length of service, in efficiency of service. Some of them have solved problems exactly similar to yours. Let a Goodyear-trained belting man tell you about it. No obligation. Just phone, wire or write the nearest branch.

MILLERS AND DEALERS IN
CEREALS, GRAIN AND FEED
JARVIS STREET & ESPLANADE
TORONTO

The Goodyear Tire & Rubber Co. of Canada, Ltd., Toronto, Ont. — Nov. 15th, 1919

Gentlemen:—

About five years ago we bought our first Goodyear Extra Power Belting. To-day half our belts are Goodyear Extra Power, and as fast as old belts wear out we are replacing them with Extra Power. The performance of the first belt has brought about this change.

We were having trouble with our corn degerminator. Every now and then the machine would stick. Although we were using the highest priced belts we could buy, they continually burnt through when the sudden load of a sticking degerminator came. One expensive belt went in two days. The next one lasted but little longer. Then we tried a Goodyear Extra Power Belt. IT gave us 18 months' service. When the degerminator stuck, Extra Power just seemed to buckle down to the job and pulled right through the peak load. It wasn't long before we decided to use Extra Power Belts on all our equipment.

Now we have installed them on grinding mills, corn mills, shaft drives, etc.

We figure that we save a great deal in price, save power, and get surer service.

Yours very truly,
The Chisholm Milling Co., Limited

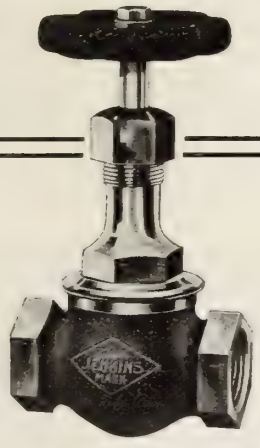
Jenkins Valves

Jenkins Valves bear the Jenkins "Diamond Mark"--a valve without it, isn't a "Jenkins."



Jenkins Valves wear longer and cost less for upkeep.

Knowing valve requirements and meeting them with a valve strong and heavy enough to stand the severest strain possible makes Jenkins valves DEPENDABLE.

They hold absolutely tight under steam, water, air or gas pressure, for remarkably long periods of service without attention, reducing upkeep costs to a minimum.

The design is heavier than the usual commercial standard pattern of other makes, enabling us to guarantee them for 175-lb. steam or 250-lb. water-working pressure. All are fitted with renewable Jenkins discs made of a softer composition than the metal, and which will seat perfectly tight in spite of inequalities or rough spots in the metal surfaces.

Jenkins' Valves are furnished in brass or iron body, in Globe, Angle, Cross, Check, Y or Blow-off, Hose, Whistle and other patterns.

An unfailing combination is Jenkins Discs in Jenkins Valves. Your supply man can serve you—but to make sure of the genuine—look for and demand the Jenkins "Diamond Mark." It is your guarantee of securing the ***genuine*** *article.*

A Water Dynamometer Which Simplifies Testing

Accurate Data Are Obtained Through the Use of Froude Water Dynamometer. Its Sensitiveness and Accuracy Lending Themselves to the Most Refined Tests

THE accompanying illustrations show the use of the Froude water dynamometer as developed at Worchester, England. One of these water brakes was utilized for testing a 950 h.p. Diesel engine at Turin, Italy, and much larger engines than the above have been tested without difficulty.

This water dynamometer was originally designed by the late Mr. William Froude for use in his experiments on the propulsion of ships. An earlier form of hydraulic brake took the shape of an ordinary centrifugal pump, the resistance to rotation being regulated by a valve placed in the outlet pipe. The apparatus was rather cumbersome in comparison with the power which could be absorbed, particularly at low speeds, and the range and method of regulation were not very satisfactory.

To meet these difficulties, Mr. Froude invented a new form of rotor and casing, which gave a greatly increased resistance for brake shaft. Each face of the rotor is formed with a semi-elliptical annular channel divided into a number of compartments by means of oblique vanes. The corresponding faces of the casing are also formed with similar channels divided in the same way.

The channels on the rotor and casing thus form two complete annular channels of elliptical cross section, each channel being divided as stated above into compartments by means of the oblique vanes. When in action the water in each annular channel is rotated continuously by the centrifugal force imparted to it by the rotor, and passes from one compartment into the next, and so on. An extremely high speed of rotation of the water is obtained, and the power put into the dynamometer is by this means converted into heat which passes away in the water leaving the machine. The motion of the water causes the rotor to re-act on the casing, which tends to turn on the friction rollers.

This is prevented by means of an extension arm working between stops, at the end of which are the balance weights by which the actual power put into the dynamometer is measured. The friction rollers supporting the casing are mounted on ball bearings and the machine is thus very sensitively balanced and great accuracy is assured. It will be understood that the friction of the dynamometer shaft in its bearings and packing glands re-acts on the casing and is measured at the end of the arm so that no error is introduced on this account.

It is of interest to note that there are many types of water dynamometers used, one form being suitable for absorbing power when running in one direction of rotation only. At the same time this machine can be run in the reverse direction for any length of time without any ill-effect (provided it is filled with water). The brake is fitted with two couplings and may therefore be used for testing engines running in either direction by coupling up alternate ends of the

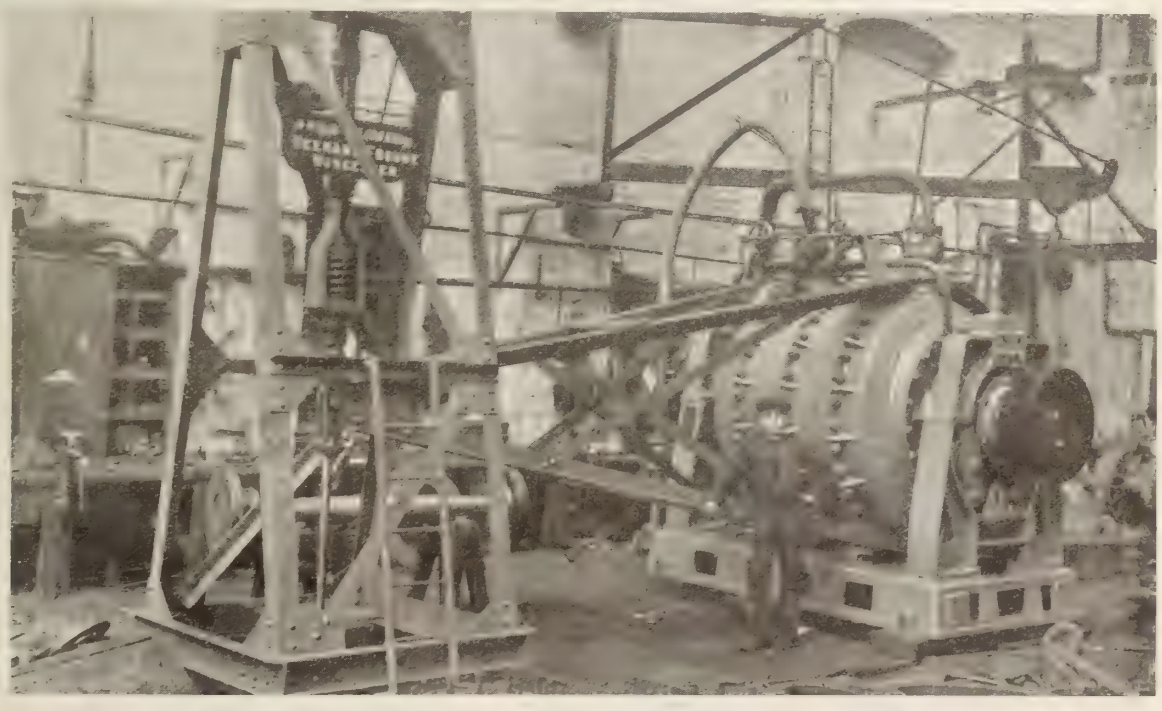

FIG. 1—FROUDE HIGH-POWER DYNAMOMETER SHOWING GENERAL ARRANGEMENT OF ASSEMBLY.

brake shaft. In the same way the machine may, if necessary, be used for testing reversible engines by turning the body of the brake round in order to make a test in the reverse direction.

These water brakes are divided into two classes, high duty and low duty machines. Generally the high duty and low duty brakes of corresponding sizes are of the same overall dimensions. The difference lies almost entirely in the different materials used in their construction. For example: A high-duty brake has a steel rotor and steel casing, whereas a low-duty brake has a steel rotor and a casing of special quality of cast iron. In addition to these brakes, there are reversible machines provided, i.e., brakes which may be used to absorb power in both directions of rotation at one coupling up.

The water dynamometer can usually be accommodated in an ordinary test house without any difficulty. In some cases a special pit is made in which internal combustion engines are tested. This machine, instead of carrying cast iron weights at the end of the arm, is arranged to pull downwards on to a special weighing machine. This weighing machine may swivel round the end of the dynamometer arm so that the overall space taken up is actually very small.

In general, for testing steam or internal combustion engines running at moderate speeds, a solid coupling is used and provision is made on these brakes so that after the coupling on the machine has been approximately lined up with the coupling of the engine to be tested by arranging suitable foundation the final lining up may be easily and accurately made. For this purpose the rollers or bearings carrying the brake body are adjustable in both horizontal and vertical directions. This is found to be a great convenience. Some use flexible couplings even for the larger sizes of brakes. In this case a coupling having rubber, gutta percha, or raw hide bushes fixed round the coupling bolts is often used. For testing high-speed internal-combustion engines it is always advisable to fit a flexible coupling.

As to water supply for the water dynamometer, it is pointed out that provision should be made for an ample supply of water to the brake. Usually a pressure of from 15 to 20 lbs. per square inch is sufficient, and for slow speed work a pressure of 10 lbs. per square inch is often enough. For very high speed work it is sometimes necessary to allow a greater pressure. The minimum consumption of water amounts to about two gallons per B.H.P. per hour, but the makers recommend that allowance should be made for three gallons per hour for each B.H.P. to be absorbed. Water may leave the brake at any temperature up to 150 deg. to 170 deg. Fahr., or 65 deg. to 75 deg. Cent.

As to the regulation of the load, these brakes are designed to automatically maintain a constant torque. The power absorbed by these machines depends to a great extent on the quantity of water in the brake. When the position of the inlet valve is fixed the load is regulated by an automatic outlet valve which may be relied upon to give an absolutely constant torque in spite of variations in the pressure of supply. In the case of smaller machines intended for testing petrol engines the brakes are always full of water, and the power absorbed is regulated by a system of sluices. These sluices consist of two discs of metal which are interposed between the rotor and the casing so as to regulate the amount of working surface which is in action.

It may be of interest to note the details of the calculation of the horsepower. These brakes are arranged so that the horsepower may be very easily calculated by noting the weight at the end of the arm and the speed of the engine. Machines may be arranged to give the results either in the British unit of 33,000 feet lbs. of work per minute, or in the metrical unit of 75 kilogrammemetres per second. In either case the length of the dynamometer arm is arranged so that by the aid of the simple constant "K" the horsepower can be calculated from the following formula:

$$\text{H.P.} = \frac{W \times N}{K}$$

Where

W = Load at end of dynamometer arm.
N = Revolutions per minute.
K = Constant.

For example: In the case of a machine built to British standards, having an arm 5 ft. 3 1/40 in. long—K = 1,000. For a metrical machine having an arm 1,432.4 mm. long—K = 500.

Regarding the reversible dynamometers, it may be stated that although the above dynamometers may be used for testing engines running in both directions of rotation by alternately coupling each end of the dynamometer shaft, it is sometimes necessary to test reversible engines in both directions of rotation at the same coupling up, and there have been built a number of brakes for this purpose. There are two types of reversible dynamometers. The single rotor reversing brake has one rotor; the vanes on one side being inclined in an opposite direction to the vanes on the other side, so that one face of the rotor is working when the brake is running in the forward direction, and the other face is working when the brake is running in the astern direction.

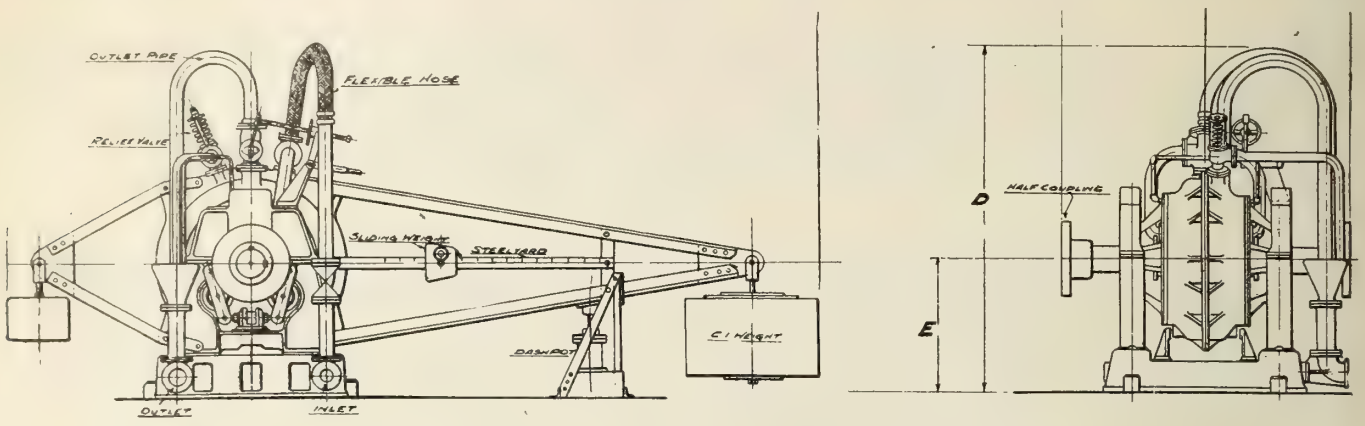

FIG. 2—WATER DYNAMOMETER.

The single rotor reversing brakes have a ball thrust bearing on an extension of the brake shaft to deal with any hydraulic thrust which is set up. The measuring apparatus on this reversible brake is somewhat different to the apparatus fixed on the non-reversible machines. A stand, built up of steel sections, carries a suspended weighing machine from which hangs a heavy cast iron weight. The arm of the dynamometer is arranged so that the reading on the weighing machine is increased or decreased according to the direction of running, and the effective torque is thereby measured.

The double rotor reversible brakes are for powers not within the capacity of the single rotor machine, and for speeds which make it inadvisable to use a thrust bearing. These brakes are fitted with two separate rotors, and of course such a machine is more expensive to build than the single rotor brake. One rotor is used for working in the forward direction, and the other for working in the astern direction. This type of brake has been largely used at the works of Messrs. Fried. Krupp, Kiel Gaarden. In neither of these reversible brakes is an automatic valve fitted to the outlet, and it is necessary to provide water for the brake at a steady pressure.

As to the application of the water brake for testing petrol engines, it is claimed that this brake provides the cheapest and most reliable method of

obtaining absolutely accurate knowledge of the output of a motor at various speeds. The water used for the braking action carries away with it all the heat generated by the dissipation of power. There is therefore no question of trouble due to heating up or seizing of the brake. These brakes are often used for endurane tests, and run as long as four weeks continuously night and day.

For gasoline engine testing the machine can with advantage be made portable. In many test shops the engines are mounted for testing side by side in a series of cradles. A very convenient arrangement for utilizing the Froude dynamometer is to lay a light track alongside these cradles on which the trolley carrying the brake may run. The brake can be run from one engine to another and coupled up by means of a flexible coupling. The power absorbed is registered on a spring balance. By means of a simple chart hung in a prominent position in the test house, the horsepower corresponding to the readings can be read off instantly. Within the space of a few minutes the engine can be tested at half a dozen different speeds with absolute and perfect accuracy. As soon as an engine has been tested the brake can quickly be uncoupled and pushed along on its rails to the next engine; this gives a speedy method of subjecting each motor to a short test, and is very convenient in large works where a number of motors are passing through the testing shop continuously.

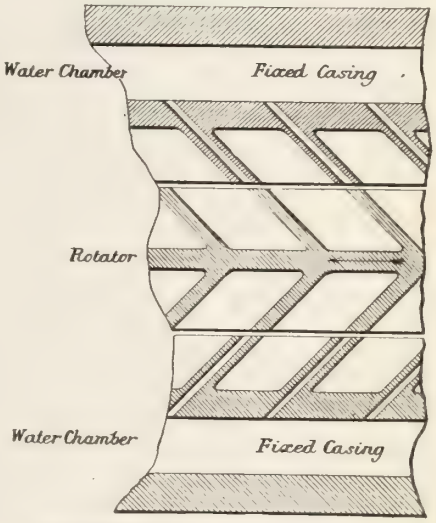
The application of the machine as a simple brake is of interest for use in cases where it is desired to absorb but not to measure the power. Amongst other applications may be mentioned brakes for use in connection with aerial ropeways, raising and lowering gear in mines, and on board ship in connection with the laying of marine cables. As the heat generated by the absorption of power is continually carried away by the water passed through the machine, the brake may be relied upon to run for any length of time without trouble. The machines built for this purpose are arranged so that the resistance varies as the square of the speed. The result is that when the machine has been set to give a certain resistance at a certain speed, any tendency for the brake to over-run is counteracted by the rapid increase in the torque caused by a slight increase in the speed. The result is that the brakes provide steady running in spite of variations in the load.

It is maintained that all absorption dynamometers must, of course, absorb the power to be measured and convert it, either into heat by means of friction, or into electrical energy. When the power is converted into heat, solid or fluid friction may be used. Absorption brakes are divided into those which utilize solid friction, fluid friction, or electrical energy. The solid friction brakes are represented by those of the Prony brake type, which utilize ropes, steel bands, or wooden blocks applied to a fly-wheel, to create the necessary resistance. They are very limited in power even when water cooled, on account of the difficulty of getting rid of the heat with sufficient rapidity to prevent the brake becoming overheated.

The solid friction brakes have been used up to as much as 100 horsepower and even more, but become very cumbersome when the power to be absorbed exceeds 30 to 40 horsepower, especially when the speed is low. Such brakes often impose a strain on the bearings of the engine under test by reason of the loads which the engine shaft is called upon to carry. There have been known cases where the bearings of petrol engines have had to be completely renewed after running tests with a brake of the Prony type. The wear of these brakes is rapid, and it is difficult to maintain the resistance constant for any length of time without very careful attention. The resistance is also apt to be very jerky, and the brakes require very careful watching to prevent accident due to seizing. Another point: It is necessary to remove all the load before the engine can be started up from rest, and this is very inconvenient when it is desired to stop and re-start the engine frequently.

Electrical brakes are important absorption brakes, but it is held that the results obtained by electrical measurement are always open to argument on account of the efficiency factor of the dynamo. The correctness of the ammeter and the voltmeter also enters into consideration. The resistance cannot be maintained absolutely constant over a long run on account of the variations in the current produced, due to the change of temperature of the dynamo, and also on account of difficulty in maintaining the resistance in the external circuit constant.

It is pointed out for small powers, the dynamo is sometimes mounted bodily on bearings, and the torque between the armature and the field coils measured by means of an extended arm and spring balance. But this method of application is limited to comparatively small powers. Here again there is trouble in maintaining the load constant. The range of speed and power which can be obtained from a dynamo is rather limited. Also for high speed work the momentum of the rotating parts of the dynamo is considerable.



ARRANGEMENT OF WATER PASSAGES.

As proof of the scientific accuracy of these brakes, it may be mentioned that Professor Osborne Reynolds of the Victoria University used a brake of this type to investigate the correct value of the mechanical equivalent of heat in foot pounds, and the figure now used, viz., 778, was established by this test.

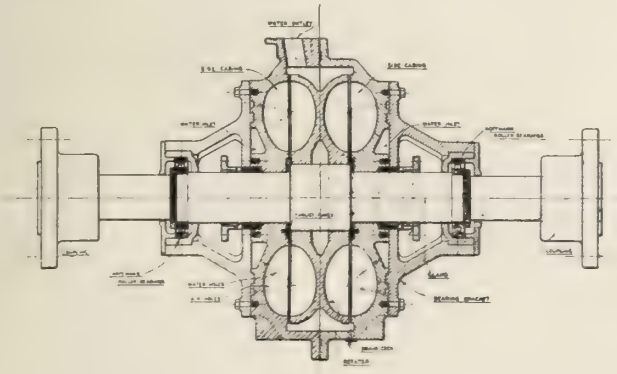


FIG. 3—SECTIONAL ELEVATION.

RAPID ROAD CONSTRUCTION

A new type of road repair equipment has been produced by a leading British firm. It consists of an electric battery-driven truck, on which is mounted a compressed air plant operated by an electric motor. Current can be supplied to the motor either from a storage battery or from the street electric mains. An air received and a special water-cooling arrangement are supplied, so that no separate water supply is necessary. The frame carrying the motor, compressor, receiver, and water tank can be raised on four jacks, and the electric truck can be used for other purposes, while the equipment is at work. Special types of pneumatic tools are supplied for breaking up road foundations and for tamping, the speed of operation being far in excess of anything possible with manual labor.

The Chemical Treatment of Boiler Feed Water

The Author in the "Stevens Indicator" Gives a Report on This Subject Which is Well Worth Reading. The Various Methods in Common Use Are Outlined and a Description of the Manner in Which They Work is Given

By E. ECHIKSON

ONE of the most important elements in the generation of power by the steam engine is the water from which the steam is made. The vast amount of energy consumed throughout the world entails the use of millions of gallons of water, and it is not surprising therefore that the quality of this most important substance should be a subject of extensive investigation. The user of power does not, however, always recognize the vital importance of the matter and as a result suffers a loss which seriously detracts from the efficiency and economy of plant operation. The presence of a few grains of solid matter in the feed water, invisible even to the naked eye, does not appear to him a controlling factor in the successful operation of a boiler, but, when he is made aware of the effects of these impurities, he cannot but recognize that the apparent molehill is really a mountain. This matter of feed water purification is consequently one of intense practical interest, and a reasonable knowledge of the subject, coupled with action upon that knowledge, will very possibly place a big item on the right side of the balance sheet.

Due to the continuous boiling and concentration which goes on in a boiler, there result four distinct boiler troubles. The first, and probably the most important, is the formation of scales. Particles of solid matter are dissolved in all natural waters, and when subjected to heat they are thrown out of solution and precipitated as scale. Such a deposit has a heat resistance twenty or thirty times as great as iron, and though it might form an excellent heat insulator for the outside of a pipe, it is very decidedly out of place on the inside of a boiler. The resulting loss of economy and capacity is, however, of secondary importance compared to the danger of overheating. Because of the presence of the scale the water cannot reach and cool the tubes. The latter may become red hot, and in their weakened state, explode.

Next in importance to scaling is corrosion, which arises from the use of water containing acids, strong acid salts, fatty oils, or organic matters. Distilled water or condensed steam also has a distinct tendency to dissolve iron, and when used, must be diluted with some raw water. The probable effects of corrosion are evident.

The nature of the impurities in the feed may be such as to cause foaming, the filling up of the steam space with unbroken bubbles of steam, or priming, which occurs when the steam carries water with it. The two usually occur together and manifest themselves by the rising and bubbling of the water in the gauge glass.

II. Sources of Water

The characteristics of a water are determined largely by the source from which it is drawn, and it is convenient therefore to distinguish the following three broad classes of supply.

(1) *Rain Water*—This water is very soft, but due to the fact that it contains dirt from the air and from factory roofs and that it is difficult to collect in sufficient quantity, it is practically unavailable as a boiler feed water.

(2) *Surface Water*—This water is taken from lakes, streams and artificial reservoirs which are fed by the slopes of hills. It is sometimes slightly acid, but is never hard, because it has not penetrated below the surface and so dissolved any lime or magnesium salts.

(3) *Ground Water* may be obtained from springs and wells. It is usually clear in appearance, but is hard, due to the taking in solution of mineral salts from the earth through which it has passed. The nature of the impurities in such water depends, of course, upon the composition of the strata from which it is drawn, the hardest waters usually coming from beds of gypsum and magnesian limestone.

III. Scale Prevention by the Three "General Processes"

It is evident from the above that every water will require individual treatment, and that a process which is suitable for the purification of one supply may be useless when applied to another. An analysis of the water by a competent chemist is absolutely essential to the success of a softening plant, and upon his report must be based the choice of a proper chemical reagent.

The three general chemical processes in use for water softening are:

(1) *The Lime (Clark) Process.*

(2) *The Soda Process.*

(3) *The Combined Lime and Soda Process.*

The Lime Process is used where the water contains bicarbonate of calcium and magnesium. It consists in the addition of calcium hydroxide, usually in the form of limewater. This limewater combines with carbon dioxide, which may exist in the free state in the water, or combined in the above mentioned bicarbonates, forming insoluble normal calcium or magnesium carbonates. The soluble bicarbonates, having lost a part of their carbon dioxide, are converted to the insoluble normal carbonates and precipitated according to the following reactions:

$$CaH_2(CO_3)_2 + Ca(OH)_2 = 2\ CaCO_3 + 2\ H_2O$$

$$MgH_2(CO_3)_2 + Ca(OH)_2 = MgCO_3 + CaCO_3 + 2H_2O$$

If any ferrous bicarbonate ($FeH_2(CO_3)_2$) is present, it will be acted upon in the same manner as the bicarbonate of magnesium. It is believed that with an excess of limewater the magnesium salt is changed to magnesium hydroxide ($Mg(OH)_2$). As this salt is also insoluble the effect is the same as in the case of the simpler action, but it allows a little latitude in the quantity of reagent to be used.

The Clark process does not affect calcium sulphate in any way. The limewater does, however, react with magnesium sulphate:

$$MgSO + Ca(OH)_2 = Mg(OH)_2 + CaSO_4$$

From this reaction it is seen that, although the magnesium is precipitated as the insoluble hydroxide, an equivalent amount of calcium sulphate is introduced, and inasmuch as this compound is in many ways more objectionable than magnesium sulphate the water is deteriorated rather than improved. The lime process is, therefore, only applicable to waters which contain bicarbonates as their chief impurity and in which amount of sulphates is small.

The Soda Process is adapted to the removal of objectionable sulphates. It is carried out by the addition of either carbonate or hydroxide of soda. When sodium carbonate is added to water containing the sulphates of calcium and magnesium, it combines with them to form the insoluble normal carbonates, leaving inert sodium sulphate as shown by the following reactions:

$$CaSO_4 + Na_2CO_3 = CaCO_3 + Na_2SO_4$$

$$MgSO_4 + Na_2CO_3 = MgCO_2 + Na_2SO_4$$

This action takes place very slowly, and unless the water is preheated, which as a rule it is not, large settling tanks are necessary. Moreover, the presence of free carbon dioxide in the water interferes with the formation of the insoluble normal carbonates:

$$CaSO_4 + Na_2CO_3 + CO_2 + H_2O = CaH_2(CO_3)_2 + Na_2SO_4$$

The bicarbonate may be reduced to the carbonate by heating.

Caustic soda acts more quickly than carbonate of soda, and, though the results are better when the water is preheated, the speed of the reaction is usually sufficient to produce fair results. If the water to be treated contains no free carbon dioxide or bicarbonates, the caustic soda will react directly with the magnesium salts to form insoluble mag-

nesium hydroxide. It will not, however, precipitate the lime salts, because calcium hydroxide is freely soluble. If, on the other hand, the water does not contain free CO_2 the soda is believed to combine with this gas to form sodium carbonate, and the reaction outlined in the previous paragraph then takes place, Collet, however, believes that sodium hydroxide reacts with calcium sulphate and forms the soluble calcium hydroxide. This calcium hydroxide then reacts with CO_2 to form insoluble calcium carbonate:

$$CaSO_4+2NaOH=Ca(OH)_2+Na_2SO_4$$
$$Ca(OH)_2+Na_2SO_4+CO_2=$$
$$CaCO_3+H_2O+Na_2SO_4$$

If the carbon dioxide necessary to complete the above reaction is drawn from bicarbonates, the softening power of the soda is doubled:

$$CaH_2(CO_3)_2+CaSO_4+2NaOH=$$
$$2\ CaCO_3+Na_2SO_4+2\ H_2O$$

If, however, there is an excess of carbonic acid available, all of the bicarbonates will not be decomposed, and some method must be used capable of purifying a water containing fairly large quantities of both sulphates and bicarbonates. The combined lime and soda process is employed in such cases.

This *Combined Process* consists simply in adding enough soda to decompose the sulphates and sufficient lime to absorb the excess carbon dioxide:

$$CaH_2(CO_3)_2+CO_2+CaSO_4+Ca(OH)_2$$
$$+2NaOH=3CaCO_3+Na_2SO_4+3H_2O$$
$$2CaH_2(CO_3)_2+CaSO_4+Ca(OH)_2+$$
$$2NaOH=4CaCO_3+Na_2SO_4+4H_2O$$
$$CaH_2(CO_3)_2+CO_2+MgSO_4+$$
$$2Ca(OH)_2+2NaOH=3CaCO_3+$$
$$Mg(OH)_2+Na_2SO_4+4H_2O$$

The chlorides and nitrates of lime and magnesia act like their sulphates and may be removed in the same way. By varying the proportion of the lime-water and the caustic soda, almost any water containing mineral impurities may be deprived of its scale forming ability.

IV. Corrosion

In the foregoing paragraphs I have discussed briefly the action and removal of impurities which are essentially scale-forming materials. There are, in addition, found in water substances which are just as objectionable and as difficult to remove, namely, corrosive agents. As mentioned above, they may consist of materials which yield organic acids when acted upon by hot water, mineral acids, and certain metallic salts like magnesium chloride. When corrosion is due to the presence of organic matter (and oils), the best remedy is mechanical filtration, and this is a problem for the mechanical engineer rather than the chemist. Mineral acids rarely occur in any considerable quantities in natural waters, but, when they do, the effect of such re-agents as lime, when used in softening, is to neutralize them. Magnesium chloride is usually removed by the soda process, although lime is also effective:

$$MgCl_2+Ca(OH)_2=CaCl_2+Mg(OH)_2$$

The hydroxide of magnesia is precipitated and the calcium chloride remains in solution. Provided there is no magnesium sulphate present, this calcium chloride is harmless.

The corroding action of magnesium chloride presents, however, a more interesting case than the comparatively simple matter of its removal. There are two distinct theories as to the operation of this troublesome salt in eating away the iron of a boiler. The more usual one assumes that magnesium chloride is decomposed at high temperatures and gives off chlorine. The magnesium unites with the oxygen of the water and forms insoluble MgO which is precipitated. The chlorine combines with hydrogen and forms hydrochloric acid, which immediately begins to corrode the iron. This view of the matter is attacked by Ost on the ground that, when water containing magnesium chloride is distilled, even at high temperatures, there is no evidence that magnesium chloride decomposes. On the other hand, experiments showed that when hot water strikes the iron surface of a clean boiler a black crust of ferrous hydroxide ($Fe(OH)_2$) is formed. Ost, therefore, concludes that with hot water iron forms ferrous hydroxide and that the magnesium chloride then reacts with the iron hydroxide as shown:

$$MgCl_2+Fe(OH)_2=FeCl_2+Mg(OH)_2$$

The sulphate of magnesium would act in the same way.

If any calcium carbonate is present, it combines with the iron chloride and forms ferrous carbonate and calcium chloride. Calcium chloride then reacts with magnesium sulphate, thus reproducing the original amount of magnesium chloride and giving in addition the objectionable calcium sulphate. It is this series of actions which explains why a very small amount of magnesium chloride can do a large amount of mischief, while at the same time it remains unaltered in quantity. It should be noticed, however, that the presence of magnesium sulphate is essential to the carrying of this cycle of changes.

The next boiler trouble to claim our attention is foaming and, associated with it, priming. The causes are given by Carney as

1. Sodium Salts.
2. Mud or Suspended Matter.
3. Organic Matter.

There is no practical way of removing sodium salts, but mud and organic matter can be removed by filtration. A chemical process is, however, sometimes applied to the extraction of suspended matter. Commercial aluminum sulphate ($Al_2(SO_4)_3.18H_2O$), or Alum, ($Al_2(SO_4)_3.K_2SO_4.24\ H_2O$), is added to the water to be clarified. The sulphate radical displaces the carbonate radical of any calcium or magnesium salts dissolved in the water, forming calcium sulphate which is precipitated. The alumina is precipitated as flocculent and sticky aluminum hydroxide which envelops the particles of foreign matter and mechanically removes them. It is evident that this reaction can take place only when alkalies are present to combine with the sulphate radical. If carbonates of lime and magnesium are not naturally present in the water, the addition of caustic soda or sodium carbonate will cause the precipitation of the alumina.

VI. Water Softening Plants

In carrying out the above methods of correction of boiler troubles by chemically treating the feed water, the addition of the chemicals in an effective manner is a matter of no small moment. Irregular treatment, such as would be obtained by non-automatic feeding of boiler compounds, is not nearly as efficient as the use of the well-known water softening installations. Of these there are many different kinds, but in general principle they may be divided into a few groups, typified by the products of several well-known manufacturers. I shall, therefore, in concluding this paper, briefly describe the construction and mode of operation of the Kennicott, Scaife and We-Fu-Go water softening plants.

In the Kennicott system the hard water first enters a raw water chamber which is placed above a box containing a water wheel. The water falls on the wheel, and, in so doing, generates the power necessary for stirring up the chemicals. These are placed in an adjoining mixing tank containing a paddle wheel stirrer. A part of the raw water flows into a dividing box, which separates the stream into two parts, one of which is thrown back into the main hard water stream, and the other of which is directed into the regulating tank. As the level of the water rises, the regulating tank float also rises and in so doing lowers the mouth of the lift pipe into the reagent tank and allows the chemicals to flow out. As the amount of water fed to the regulating tank depends on the head of the main hard water stream, it is evident that the proportion of chemicals to water is automatically kept constant. From the reagent tank the chemicals flow to the top of the reaction cone, where they meet the hard water. This reaction cone is merely an inverted funnel-shaped affair placed inside of a cylindrical tank. Around the neck of the funnel and occupying the annular space between the funnel and the tank is a layer of filtering material. When the water has passed down the inside of the cone and up around the outside, the action of the chemicals, which is continuously taking place, has succeeded in precipitating the foreign matter. It remains only for the overflow through the filter to complete the softening action by removing all suspended particles. The water is then ready to be fed to the boilers.

In the Scaife system the feed water first passes through a heater where it

attains a temperature of about 200° F. Due to the driving off of carbon dioxide, the carbonate of lime and magnesium are precipitated and are deposited in removal pans inside the heater. The water is pumped from the heater into a large precipitation tank where the necessary chemicals are added by small pumps. The chemical tank from which these pumps draw their supply is of sufficient size to hold all the material necessary for a ten or twelve hour run, and the apparatus therefore needs practically no attention except the addition of the reagents once a day. In the precipitating tank the acids in the water are neutralized and the removal of scale-forming materials is completed. As a final precaution the softened water is filtered before being sent to the boilers in order to eliminate any possible suspended matter. This apparatus has the desirable characteristic of being continuous in operation and, at the same time, accomplishing its purpose without retarding the outward flow of the feed water.

The We-Fu-Go apparatus represents what is known as an intermitent type of softener. In this system the water supply first is run into the settling or treating tanks where it is agitated in contact with the softening reagents by means of a two-armed paddle at the bottom of each tank. The water next flows by gravity to the filters, which remove all particles of solid matter which have not settled in the treating tanks. From the filters the water is pumped to a clear water storage reservoir and thence through an open heater to the boilers.

EXPERIMENT STATIONS OF THE BUREAU OF MINES

In connection with the work of the United States Bureau of Mines, Department of the Interior, the bureau is now conducting eleven mining experiment stations, located in various mining centres of the country, and bending their energies toward the special mining problems that are local to their part of the country. So great has been the demand for knowledge concerning the character of the work undertaken at these various mining stations and its general relation to the mining industry, the bureau has issued a bulletin describing the work of the stations.

Dr. Van H. Manning, director of the bureau, sketches the work of the different stations as follows:

"The station at Columbus, Ohio, situated at a lay-working centre, is employed mostly on ceramic problems. In this country there are about 4,000 firms manufacturing clay products, including brick, tile, sewer pipe, conduits, hollow blocks, architectural terra cotta, porcelain, earthenware, china and art pottery. The amount invested in these industries is approximately $375,000,000, and the value of the products exceeds $208,000,000 annually.

"The station at Bartlesville, Okla., is investigating problems that arise in the proper utilization of oil and gas resources, such as elimination of waste of oil and natural gas, improvements in drilling and casing wells, prevention of water troubles at wells, and of waste in storing and refining petroleum, and the recovery of gasoline from natural gas.

"What the Bureau of Mines has done for the great coal-mining industry, chiefly through investigations at the experiment station at Pittsburgh, Pa., has been published in numerous reports issued by the bureau. Some of the more important accomplishments have been the development and introduction of permissible explosives for use in gaseous mines, the training of thousands of coal miners in mine-rescue and first-aid work, and the conducting of combustion investigations, aimed at increased efficiency in the burning of coal and the effective utilization of our vast deposits of lignite and low-grade coal.

"How vast are the deposits of low-grade ores being made available through the experiment stations is shown by the work assigned to the station at Minneapolis, Minn. The primary purpose of this station is to devise methods of utilizing low-grade iron ores. It has been estimated that the reserves of low-grade magnetic iron ores in the State of Minnesota alone amounts to some forty billion tons, but until recently these ores have been untouched because no process of treating them profitably has been devised. Even now only one company is attempting to utilize them. The Minneapolis station has already demonstrated that one process for utilizing the great deposits of manganiferous iron ore on the Cuyuna Range is metallurgically possible.

"Work such as this not only stimulates mineral production and helps to make available tremendous resources that are now unused, but it increases the total wealth of the nation and ultimately benefits every citizen.

"The mining industry is so related to commerce and manufacture that the importance of publishing the results of technical investigations of mining problems is becoming more and more evident. The miner and the mine operator are integral parts of the industrial system of the country, and each needs to keep in close touch with what the Government is doing through the mining experiment stations of the Bureau of Mines.

"In the West vast quantities of low-grade complex ores will become available as soon as commercially feasible processes are devised. Many of the problems involved, which are being attacked at the Golden (Col.) station, the Salt Lake City (Utah) station, the Seattle (Wash.) station, the Tucson (Ariz.) station, and the Berkeley (Cl.) station, are of such a nature that the small operator cannot afford to attack them, and the large operator finds them outside his field. Yet the solution of any one of them may add greatly to the available resources of the country and may result in establishing a new industry that will build up the district in which it is situated. Already these stations, although young, have witnessed such results.

"To-day, through the efforts of men at the Golden station, there is an American radium industry. Formerly the low-grade radium-bearing ore was wasted, the best of the ore was bought by foreign concerns at ruinously low prices, and the radium was shipped back to this country at excessively high prices.

"The Salt Lake City station has devised novel methods of treating certain low-grade and complex ores of lead and zinc. These methods show a large saving of metal over methods hitherto employed, and have made available ores that other methods could not treat profitably.

"The Seattle station is busy with the beneficiation of the low-grade ores of the Northwest, and the mining and utilization of the coals of the Pacific States; the Tucson station is working on the beneficiation of low-grade copper ores; and the Berkeley station has shown how losses may be reduced at quicksilver plants, and how methods at those plants can be improved.

"In the conduct of these investigations the bureau seeks and is obtaining the co-operation of the mine operators. At more than a dozen mills in the West engineers from the stations are working directly with the mill men on various problems, and the results they already have obtained more than warrant the existence of the stations. Success in solving one problem may easily be worth millions to the country. Mining men are using these stations more and more freely as they realize that the Government maintains these stations to help them, and that the difficulties of the operators, both large and small, will receive sympathetic consideration and such aid as the stations can give."

Some Information Regarding Hydraulics

The Subject of Hydraulics From Both a Theoretical and Practical Standpoint is Described, Particular Stress Being Laid on the Application of This Knowledge to Fire Service

By DONALD A. HAMPSON, Associate Member A.S.M.E.

MOST men can trace their interest in the active work of fire departments back to boyhood days and the delirious joy of going to a fire with all the thrilling and noisy accompaniment. Men in the mechanical field are naturally interested in modern apparatus, its performances, and advances in the protection of life and property. In smaller cities with their volunteer fire departments and in private plants which maintain some sort of a department or other means of protection of their own, the engineering features such as the selection of new apparatus, repairs, hydraulic problems, etc., demand the assistance of someone with special training—and that someone is usually selected because of machine shop, engine room, drafting or surveying experience. With a good working knowledge of hydraulics to guide them,

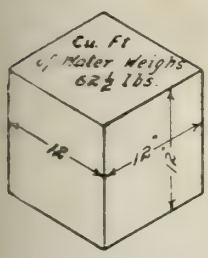

FIG. 1.

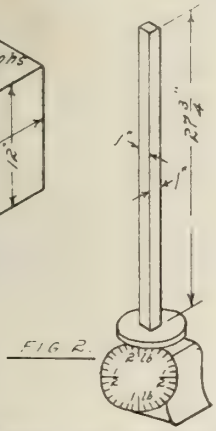

FIG. 1—ILLUSTRATING THE WEIGHT OF WATER.

FIG. 2—SHOWING COLUMN OF WATER THAT GIVES 1 LB. PRESSURE PER SQUARE INCH.

men of the machine trades are particularly well fitted to assist in this work—often at the same time gaining an unusual opportunity to appear in public life, where their business habits of getting quick, definite results in an economical manner make a unique showing alongside of the average municipal proceedings.

The Water Supply

Back of the fire department there must be a water supply. Viewed from several angles, the supply is of vital importance to all residents of a community. Except in new communities, a means of water supply has been provided, it serving for domestic, fire, and industrial uses. Many plants have their own water supply, either to assure better and quicker results in conjunction with city service or, in the case of isolated plants, to provide the only means of fire protection that is available. Whether public or private, an adequate or a seemingly too adequate supply is a measure of economy, figured in terms of insurance premiums, if in no other. Incidentally, it may be stated that the fire loss of the world in times of peace is approximately two hundred and fifty million dollars per year!

There are three common sources of water supply, i.e., the gravity system which delivers water from a reservoir on a higher elevation; standpipes which furnish a substitute for the higher elevation and into which the water must be pumped, and some arrangement of cisterns or wells from which the water is pumped into the mains. This latter system is in very limited use—the constant expense of pumping and the restricted quantity of water available making such a system of value only in special cases, though for industrial fire purposes where a positive source of power is to be had, pumps are recommended.

Villages that are not in a position to instal a gravity system, either from geographical or financial reasons, find the standpipe admirably adapted to their needs; pumps of some sort are required to keep the supply full, but it is often possible to arrange the installation in connection with some other work, thereby decreasing the maintenance expense. Standpipes are tanks, generally of metal, set upon a solid foundation on the highest elevation near at hand. Before the general introduction of elevated tanks, standpipes were often used for factory protection.

But the most widely adopted and satisfactory water supply is the reservoir, fed by rainfall alone or in conjunction with springs and streams. Its location is selected from a number of possible sites in which elevation, watershed, distance from the community it is to serve, cost of reservoir and pipe lines, and further expansion of the system are the factors weighed in making the selection. Maintenance is but a small item if the work is well done in the beginning, and it might be added that such a water system will not only pay dividends, but it will have the distinction of being the one self-supporting department in the community. A well-laid-out system will provide an abundance of water at all times, and this at a pressure that is not so high as to cause serious leaks in the piping and yet is ample for all needs.

The Part of Gravity

Gravity plays the leading part in the great drama of water. The reservoir, or gravity system depends upon this phenomenon for its action. Nearly all hydraulic calculations contain the factor of gravity or one that is deduced from it or is a substitution. The force with which the stream of water issues from the faucet is due to gravity and is the same in amount as if the water had fallen from directly overhead the same height instead of having come through long lines of pipe—there is, however, some loss in coming through pipes and around bends.

Hydraulic measurements are not made by weight but by pressure, though as just stated the weight (gravity) is the basis of pressure. In Fig. 1 we see the familiar cubic foot of water that weighs 62½ lbs. Weights of all other substances are taken from this as unity—steel, for instance, having a "specific gravity" of about 8 and weighing about 500 lbs. for a cubic foot. If we could shape water into a rod 1 in. square and have that rod 27¾ in. high, its weight upon the scales, Fig. 2, would be 1 lb.; this is an important point—it should be memorized because the length ex-

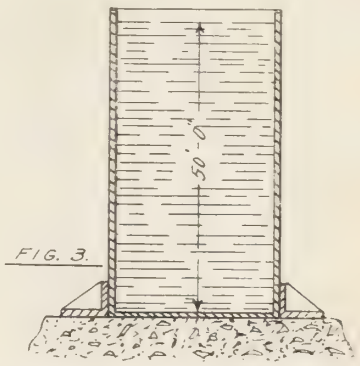

FIG. 3—TYPICAL STAND PIPE. THIS DEPTH OF WATER PRODUCES A WEIGHT AND PRESSURE OF 22 LBS. ON EVERY SQUARE INCH OF THE BOTTOM.

pressed as 2.3 feet is a frequently used factor in conversion. Our standpipe, Fig. 3, has 50 ft. of water in it—therefore the pressure on the bottom is 50 ÷ 2.3 = 22 lbs. per sq. in.

That water has weight every fireman can testify, but he seldom knows how much weight. A length of filled hose is heavier than most persons would guess; a one foot section of 2½ in. hose weighs 1½ lbs., and the water it holds, 2 lbs., making a total of 3½ lbs. as seen at Fig. 6—this is 175 lbs. for a 50 ft. length of hose without fittings! Water can be compressed but a fraction of one per cent. This property makes it invaluable in hydraulic machinery where thousands of tons pressure must be maintained. Water pressure is distributed equally in all directions as may be seen by reference to Fig. 4, where the piston in the left hand cylinder compresses the water, distributing the pres-

sure equally in all directions against the walls, as contrasted to the right hand piston which bears on a block of wood which transmits the same pressure directly and solely to the bottom.

The vertical height determines the pressure at the point of issuance. This height is called the "pressure head" or just "head"—it does not matter whether the points are directly over one another or miles distant, the vertical height

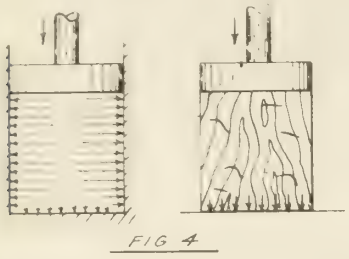

FIG. 4—AT LEFT WE SEE THAT WATER PRESSURE IS TRANSMITTED EQUALLY IN ALL DIRECTIONS. AT RIGHT WE NOTE THAT PRESSURE ON A BLOCK OF WOOD OR METAL IS NOT EQUAL.

remaining the same, the outlet pressure will remain the same, barring certain losses in the flow. Fig. 5 illustrates this point by an actual case from one city. Two hydrants were selected, one but an eighth of a mile from the reservoir and the other two miles away, but both having the same elevation, i.e., 150 feet below the surface of the water. Both hydrants are on the same 24 in. main, and according to the law of "head," both should show the same pressure, which they did without about one per cent.

Filters as a part of the municipal water system cut off some of the pressure—that because they are situated below the level of the reservoirs about ten to twenty feet and the water going into the mains partakes of a head based on the elevation of the filters. This means a loss of five to ten pounds pressure in the mains which may cut down the effective pressure for fire or high sections served so that pressure filters have to be installed, these being filters which have the pressure put back (so to speak) by pumps.

Besides weight and pressure, the factors of friction, velocity, and discharge figure largely in hydraulics. It is often said that water seeks its own level and rough calculations (?) are made upon such action. Water does seek its level but it never reaches it in any but a closed system, i.e., one where there are no discharges and where the water has time to adjust itself—the level is not reached until motion has ceased. The factors mentioned at the beginning of this paragraph are responsible for failure to reach the level in an open system.

The Hydraulic Grade Line

The height to which water will rise in a flowing system is shown by what is called the "hydraulic grade line," an imaginary line drawn from the surface of the supply to the last point of discharge; if at any point along the main, a tube were erected, the water would rise to that line—also if any part of the main rises above the line or some part of the city is above it, water will not flow there unless pumped or siphoned. Knowledge of the principle of the hydraulic grade line is of interest to firemen in noting the greater pressure at some locations than others. Fig. 7 shows an easily constructed model to illustrate and prove the principle; it will be seen that the water rises to the line; but if the outlets were plugged, the water from the tubes would spurt as high as the level in the tank.

The fireman must take the water at the hydrant as it is. The path from the main to the nozzle is usually shown as by Fig. 8, and the relative areas and capacities as shown at Fig. 9. The 4 in. pipe leading into the hydrant looks much too large for the 1 in. nozzle which the fireman uses—and it would be if the rate of flow were the same in each, which it is not, a nozzle being a device to increase the speed of delivery and thus needing a large feed pipe.

The fireman works with movable equipment—pumps, hose, and nozzles. Special formulae have been worked out for use in this connection because the standard formulae of hydraulics do not fit these special conditions. In big pipes, water flows along easily—the water in the 24 in. main at Fig. 5 loses but 1 lb. pressure in two miles of travel and it discharges over 16,000 gals. per min. (constrast this with a 3 in. pipe laid over the same stretch which would discharge only 20 gals. per min. to see the efficiency of large pipes). A familiar formula for discharge is:

$$\text{Gals. per min.} = \sqrt{\frac{D^5 \times H}{L}}$$

D in inches, H in feet, and L in yards.

Water is restricted in its flow by a number of factors such as—the resistance it offers to entering the pipe at the reservoir, friction in running through the pipe due to rough interior and confinement, bends in the pipe, branches leading off, and changes in the size of the pipe.

Friction

Friction is the big item of loss both in pipes and hose. Iron pipes are subject to a disease called tuberculation, a raising up of lumps on the interior, hastened and aggravated by an imperfect protecting coating at the time of manufacture. Tuberculation not only decreases the effective area but it makes this roughness which is the cause of so much friction. There is friction of liquids just as there is friction of solids and just as a weight is more easily shoved over a glass surface than an unplaned board, so water moves more easily through smooth vessels.

Fire hose is lined with rubber to make the interior smooth, as well as to make it waterproof. The friction of water moving inside good rubber lined hose is fully one-third less than through iron pipe of the same inside diameter. But when the lining gets worn, the friction may rise 50 per cent., showing that to get the required discharge worn hose must be replaced. This friction on the interior has been termed "skin friction."

The usual way of stating friction is to speak of it as so much loss of pressure in lbs. per sq. in. or as the pressure lost in 100 ft. of hose or pipe. In passing through a hydrant there is a loss of pressure of from 2 to 3 lbs.; and in connection with this it might be added that that is less than the friction loss in a hundred feet of good hose carrying only 150 gals. per min., showing that it is false economy to space hydrants too far apart.

Friction varies:

(1) Increases directly with an increase in length of pipe or hose.

(2) Increases directly as the inside diameter gets smaller.

(3) Increases as the square of the velocity.

(4) Increases with the flow.

Rule 4 is not commonly stated because it follows from rule 3, but it has been added here to emphasize the point, for firemen are apt to expect greater discharge than is actually realized by trying to increase velocity. As velocity is simply rate of speed, naturally more water will pass through with increased velocity, but a proportionate increase is retarded because the friction increases so rapidly. Table 1 gives the friction loss in 2½ in. hose for several rates of flow; considering eight or ten lengths of hose with a given flow and with twice that flow, we see that very little pressure can survive by the time the water reaches the nozzle.

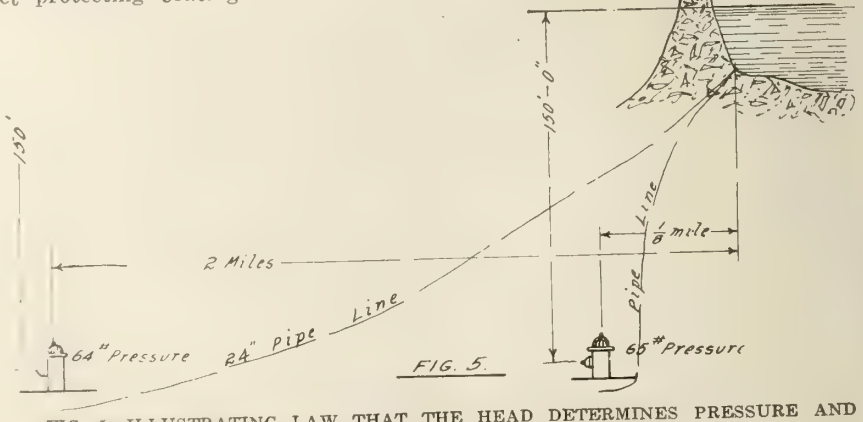

FIG. 5 ILLUSTRATING LAW THAT THE HEAD DETERMINES PRESSURE AND DISTANCE HAS VERY LITTLE EFFECT.

At the fire, the fireman has little time for hydraulic calculations. He is concerned with water where he wants it, when he wants it, and with the most speed, and to attain his ends he must practise applied hydraulics, either knowingly or not. The Siamese is a device to get the same amount of water to a

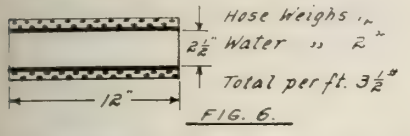

FIG. 6—SECTION OF FIRE HOSE AND ITS WORKING WEIGHT.

given point without such a great friction loss as obtains with a single line, that means more water because the velocity will not have been reduced to such a great extent. A study of the right hand column of table 1 shows at once the gain resulting from the Siamese—not to know the value of the Siamese may mean defeat at a big fire or when water is limited.

Returning now to the four rules of friction we find other chances for their practical application. Rule 1 shows why long hose lines should be avoided—thus, if there is a loss of 5 lbs. pressure in one length of hose, there will be a loss of 50 lbs. in ten lengths, which may absorb the entire pressure from the hydrant. Long lines of hose have no excuse for their existence, in most cases, except to furnish work for firemen.

Rule 2 does not affect the fireman because the size of hose and water mains have been fixed long before he arrives. Two and one-half inch hose has become standard except for the high pressure service in big cities, where 3 in. hose is used. For information it will be stated that the friction loss in 3 in. hose is less than half that in 2½ in. hose.

Rule 3 shows that if the water is forced through faster, the friction increases at an alarming rate. As previously stated in connection with flow, increasing the velocity is not always a good policy for a point is reached where the friction actually holds the water back and no gain is realized.

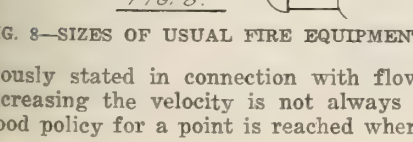

FIG. 8—SIZES OF USUAL FIRE EQUIPMENT.

Our knowledge of friction, then, tells us that more water is obtained for fire use—by keeping the lines short, by having only hose with smooth lining, and by limiting the velocity to, say, that corresponding to a nozzle pressure of 70 lbs.

Velocity

Velocity, as a rate of movement, may be expressed as feet per sec. for water, or in the case of a train, as miles per hour. There are two sources of velocity of the fire stream—"head" and pumps, which create an artificial head. Then we have nozzles which are a device to increase velocity.

Either by reason of the heat or of inaccessibility, it is seldom possible for a fireman to get within anywhere from ten to a hundred feet of the blaze—his stream of water must bridge this space and to do that effectively it must have some force to carry there. An effective fire stream is one that will pass through a ten inch circle at the point of consideration, that has not broken up into spray at that point. The effectiveness of a stream depends upon its velocity and its discharge. If a fireman pointed the open end of a length of hose toward a fire, the hose would discharge just as much water as if it had a nozzle attached, but the water would never reach the fire, it would fall but a few feet from the open butt. The reason for this and for the use of nozzles will be made clearer by a little elementary hydraulics.

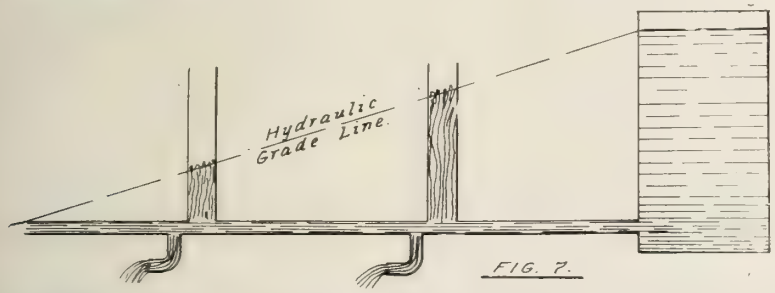

FIG. 7—MODEL USED BY AUTHOR TO SHOW THAT WATER DOES NOT RISE TO ITS LEVEL WHEN DISCHARGING. PIPES ERECTED AT ANY POINT WILL FILL ONLY TO HYDRAULIC GRADE LINE.

The common formula for a velocity is $V=\sqrt{2gh}$ where V is in ft. per sec. and h is the head in feet, while g is of course 32.16 (gravity). The principal use for this formula is in finding the velocity at a nozzle when the pressure is known, altering the formula to terms of lbs. per sq. in., as $V=\sqrt{4.6gp}$. As an example a nozzle pressure of 70 lbs. gives a velocity of $\sqrt{4.6\times32\times70}=101$ ft. per sec., which is at the rate of 70 miles per hour. A 40 lb. nozzle pressure equals 51 miles per hour, showing that a fire stream travels at a high rate. The velocity from a pipe line is affected by conditions previously named, one formula for this being

$$2.3\sqrt{\frac{h\times d}{.02\times1}}$$

Based on this formula, the pipe line of Fig. 5 should show a theoretical velocity of 98 ft. per sec., but actual tests showed it to be only 86 ft. per sec. during the day time.

500		

TABLE 1.

Nozzles convert volume into speed, just as the narrow ravine forces the brook to travel faster than when flowing through the wide meadow channel—the flow is practically the same in either case. The shape of the nozzle has much to do with keeping up the volume; thus in Fig. 10 if a hole is cut in the side of the standpipe as at A, the flow will be less than three-fourths what it would if a nozzle were applied as at B. The loss at A has been termed the "contracted vein." The velocity at the point of issuance is the same as it would be if the water had fallen a height equal to the head.

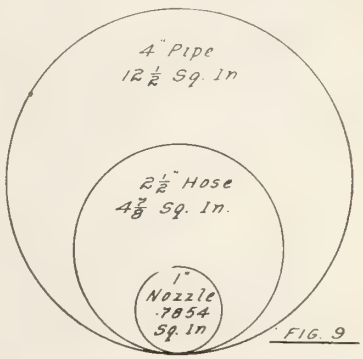

FIG. 9—ACTUAL SIZES, SHOWING ALSO RELATIVE CARRYING CAPACITY AT THE SAME VELOCITY.

As the velocity is the "get there" of the fire stream, anything that decreases it should be avoided as much as possible. Velocity is reduced by sharp bends, roughness inside the line, fittings, and changes in size. To what survives, we owe the activity of our fire streams. The range of a stream of water discharging horizontally is illustrated by Fig. 11, and calculated by the formula $R=\sqrt{4hy}$. In fire work, the streams are seldom horizontal and there is seldom any means of knowing the head, therefore, the range—or "reach"—as it is called is found from the pressure at the nozzle, and the latter determined by a gauge applied to the stream close to the point of issuance. Nozzle pressures and fire distances vary so much that tables have been prepared showing the maximum reach on an effective stream at many

NOZZLE PRESSURE.	20	25	30	40	45	50	55	60	65	70	80	90

H.	37	42	47	55	58	61	64	67	70	72	76	80

TABLE 2.

different pressures, of which the Table 2 is an abbreviation. What are called "horizontal" and "vertical" distances in the table are shown by Fig. 12. The figures of Mr. John R. Freeman, determined nearly thirty years ago, have been the recognized standard for fire streams—he fastened his hose to heavy planks for his experiments and directed them at the angles of Fig. 12.

It will be noticed from the table that

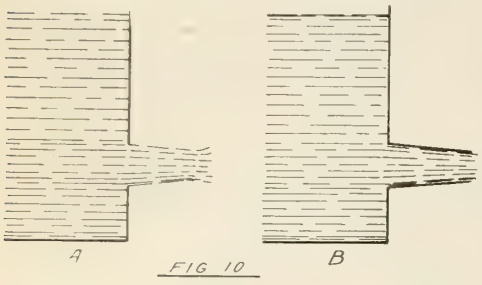

FIG. 10.

the increase in nozzle pressure is not accompanied by a proportionate increase in reach—this shows us the folly of trying to get more water, and that further, by increasing the pressure—somewhere around 50 lbs. at the nozzle is the most efficient stream. It will be also noticed that the vertical reach is greater than the horizontal. Table 2 is the reach with a 1 inch nozzle, the reach with other sizes up to 1½ inches do not vary 2 per cent. from this, showing that size of nozzle has nothing to do with reach.

Discharge

The discharge from a pipe is found from the formula to be Q=gals. per min.=.04d²×vel. Greater velocity means greater discharge both from a pipe and a nozzle. To obtain the discharge from a nozzle when the pressure is known, the formula is $D=29.7d^2\sqrt{p}$. As an example a 1 inch nozzle at 60 lbs. gives 216 gals. per min. This formula is near enough for practical results, but differs from actual discharges calibrated and compiled into tables—the tables give 229 gals. for the conditions named in the last sentence—the use of co-efficients brings the computed discharge up to the tables, but as it is difficult to remember these for all conditions, $D=30d^2\sqrt{p}$ is sufficiently accurate for field work. Due to the contraction named and shown by Fig. 10, an opening of the sort at A or the flow from a hose end—open butt—is materially reduced from that if some form of nozzle is provided, the open butt showing a discharge of only 70 per cent.

It is often desirable to know the discharge, but the nozzle pressure is not known though the pressure at the hydrant or the pump is. The discharge through lines of hose depends upon their layout—long lines of hose, hose carried up ladders, and sharp bends cutting down the discharge very much; in such cases the pressure at the hydrant or at the pump, if one is being used, does not indicate the ratio of discharge—it indicates certain operating conditions which build up the pressure at that point. This pressure may be used to find the discharge by the use of a formula in which N.P. is the nozzle pressure, E.P. is the pump or hydrant pressure, L the number of 50 ft. lengths of hose, and K a constant from the table 3.

$$\text{Then N.P.} = \frac{\text{E.P.}}{1.1+KL}.$$

An example is 2 lines of 2½ inch hose Siamesed into a 1½ inch nozzle with the pump showing 140 lbs. The N.P. then will be

$$\frac{140}{1.1+135\times 2} = 104 \text{ lbs.}$$

Knowing the nozzle pressure and the size bore, the discharge can always be found by the formula previously given, for our example $D=30\times 1\frac{1}{2}^2\sqrt{104}=$ 681 gals. per min.

The constant K has to be selected according to the number and size of lines and the bore of the nozzle. Only values for 2½ inch hose have been given in this table. Sometimes the nozzle pressure is known and the hydrant pressure is not and it is desired to form an idea of the latter; in such a case the discharge formula is translated into E.P.=N.P.×1.1.+KL.

It takes pressure to get water through long lines of hose with their friction and up ladders with the loss of head and weight of water and through small nozzles converting to velocity. A few localities have sufficient pressure for any fire demands, but most cities do not and the water in the mains has from 20 lbs. to 60 lbs. pressure. Pumps of the stream or motor-driven variety must then be employed for fire departments and power pumps for industrials. Pumps increase pressure—they are usually capable of increasing it beyond what hose will stand for long.

As has been said, the gauge on a pumping engine is indicative of the work the machine is doing—not of the amount of water the firemen are getting. That should be firmly fixed in mind. Enthusiasm in volunteer departments turns often to getting a high pressure at the machine instead of water on the fire. A couple of good, effective streams on the fire are better than a dozen poor ones. The same enthusiasm frequently leads to the laying of so many lines that none delivers an effective stream. The writer has seen first-class pumpers virtually useless because placed where the supply had already been tapped by many hand lines of hose—the pumper could get but little water, and this it was distributing through long lines to fearless men who couldn't reach above the first floor. Very likely the taxpayers of that community would be asked to enlarge the water supply, when the whole trouble is lack of knowledge of hydraulics by those in charge.

NOZZLE SIZE.	1 – 2½" LINE.	2 – 2½" LINES SIAMESED	3 – 2½" LINES.

TABLE 3.

Lines which are carried up ladders or through water towers or standpipes do not discharge the amounts of the formulas given unless first the engine pressure is decreased by an amount which is the height of rise multiplied by .434. The gain in carrying a line up a ladder or in a building is that of obtaining a better point for play of the stream—there is no gain of velocity or discharge.

Where there is a pumper, it is of interest to know its capacity as compared to the delivery of the main from the reservoir or as compared with some stream that may flow through the town and which might be called upon to supply water for a serious fire. Very few streams of size that have not had their flow measured at some time or other—suppose that it was found to be 31,000 gallons per minute—that would equal the rated capacity of thirty-one pumpers of standard 1,000 gallon capacity; or,

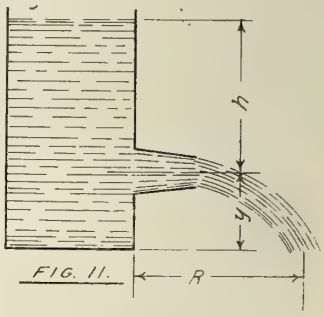

FIG. 11.

considering the main in Fig. 5, that will deliver about 10,000 gallons per minute, which equals the delivery of ten machines of the assumed capacity.

The selection of the best kind of pump is a matter of local conditions. A pump for stationary fire service may be of the gear type, centrifugal, or piston pump, the triplex pump of the latter type being highly in favor with the underwriters. The matter of drive for the pump has much to do with the type selected; for instance, the centrifugal pump makes a good outfit in combination with either an electric motor or a steam turbine for the drive is direct connected, and such a set is compact and efficient.

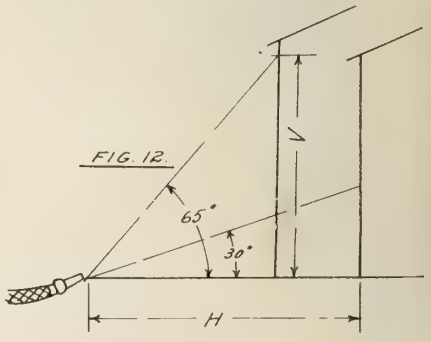

FIG. 12.

For use of the fire department, the modern trend is almost wholly toward motorizing. The steamer which has served so faithfully in the past has been outclassed by the gasoline pumper, which by this time is thoroughly reliable, and which has far greater capacity and speed than the steamer of the same weight. Only in Northern localities is there raised an objection to motor apparatus—that of inability to negotiate snow of depth. However, at time of the heaviest snow falls it is impossible for horses to draw any but light loads, and for a team to pull a heavy steamer is practically the same. During the severe blizzard of 1915, one third-class city was so tied up that not a vehicle of any sort moved for three days, except a seven-ton motor-driven pumper, newly purchased, which the driver in his enthusiasm took from the house against orders and successfully made a round of the town.

There are the usual three types, gear, centrifugal, and piston, to select from in the purchase of a motor pump. The gear pump is used by the most manufacturers, and is well and favorably known. Its objections may be summed up as pulsations of the stream and of the hose (not serious), wear of the gear teeth, and trouble with foreign matter if drafting from open water. The centrifugal pump has all the good qualities of stationary centrifugals; the centrifugal is a velocity pump, the pressure it delivers increases with the square of the velocity of the impellers. As there are no close-fitting parts it does not deliver a positive amount of water at all times, and it will not pump at pressures much over 200 pounds per sq. in.; having no fitting parts, it cannot create a vacuum, and when drafting, has to be primed. Its efficiency is the lowest of all the pumps, 65 to 70 per cent. on the average, but its freedom from trouble and ever ready qualities make it desirable for fire service. Stationary pumps of this type are used for the high-pressure systems in all the big cities.

The piston pump, gasoline driven, has proven quite successful, one make (Ahrens-Fox) having performed a feat never attainable with the steam-driven piston pump, i.e., that of pumping water to the top of the Woolworth Building in New York.

DAYLIGHT FROM ELECTRICITY

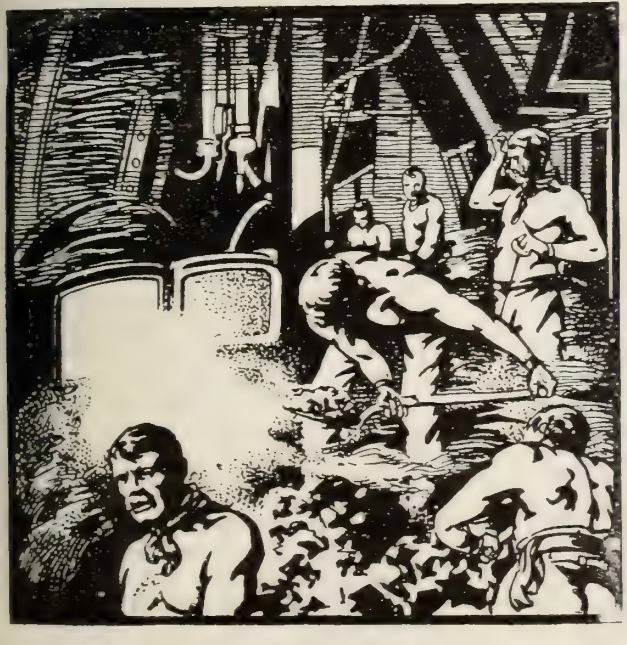
Various attempts have been made within recent years to obtain an artificial light which is near enough in tone to ordinary daylight to enable colors to be matched within accuracy. In most of these attempts screens were used to filter the light of electric lamps. Recently, however, a much more promising solution was solved by a British artist, Mr. Sheringham, in conjunction with Dr. Martin of the optical section of the Imperial College of Science, London, and Major Klein, an officer engaged on camouflage work. The device is remarkably simple. All the light from a half-watt (or gas-filled) electric lamp is thrown on to screen overhead, painted with apparently aimless splashes of various pigments. All the light obtained is that reflected from this screen and the pigments are arranged to absorb certain portions of the electric light so as to make the reflected light a close imitation of daylight. Electric light (from gas-filled lamps), is rather richer in red and yellow rays than daylight, and the pigments correct this excess. This mode of lighting has already been adopted with conspicuous success in a London picture gallery.

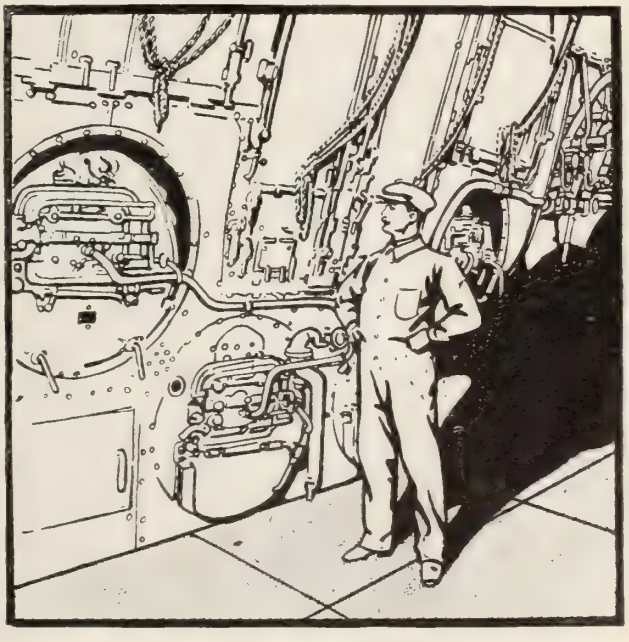
COVERING IRON WITH IRON

During the war many worn parts of aircraft machinery and motor vehicles used by the British forces were rapidly repaired in a remarkable way. The metal worn away was replaced by depositing a film of iron by means of electricity. This process was applied in the case of ball bearings and other parts, where even a minute amount of wear was so serious that scrapping would be necessary. It was also used with good results in saving from the scrap heap any parts of machinery which had accidentally been made a few thousandths of an inch too small. The problem of electrically depositing iron is a very difficult one, but the methods developed by British engineers were most successful. By means of heat treatment the deposited film becomes so closely welded to the metal that microscopic examination can detect no dividing line. Much of the research work in this matter was carried on at Sheffield University.

A BRITISH ELECTRIC "SCOOTER"

A very attractive development of the motor scooter has been made in Great Britain. Realizing the advantages of simplicity in the mechanism of this humble type of vehicle, a British firm has produced an electrically-driven model. A small storage battery is placed between the wheels and drives an electric motor of ½ horse power geared to the back wheel. Speeds up to 12 miles per hour are obtainable on level roads, and one charge of the battery will cover from 25 to 40 miles. The control is by means of a small switch actuated by rotating one of the handles. A seat is provided, and there is a road foot-rest on each side of the battery. Owing to its moderate speed, the electric scooter is intended merely as a convenient town or village runabout for occasional use, as by ladies on shopping or visiting expeditions. The final cost is expected to work out at aobut £30, and the running costs are very low, while maintenance expenses will, owing to the absence of an engine and other complicated mechanism, work out at a very modest figure.





COAL VS. OIL FIRING ON BOARD SHIP—A CONTRAST FROM THE "STEAMSHIP."

The Use of Superheated Steam and Superheaters

The Use of Superheated Steam Results in Very Material Economies in Power Plant Operation. This Article Deals With the Subject in a Comprehensive Way From Both Operating and Economic Standpoints

By ROBERT JUNE, Mechanical Engineer

THE possibilities of effecting economies in the power plant through the use of superheated steam are worthy of careful consideration in these days of high fuel and labor costs. In this connection, the fact should be recognized, at the outset, that the use of superheated steam is not necessarily confined to new plants especially designed for such operation, but that in many cases it can be successfully adapted to old plants without incurring excessive expenditures. In our discussion, it will be well to examine the effects of superheating, factors governing advisability of using superheat, temperature to which steam is to be raised, superheater construction, materials for use with superheated steam, and some details of operating practice.

Effects of Superheating

By superheating, we mean the practice of raising the temperature of steam, immediately after its generation in the boiler, to a point considerably above the saturation point, without greatly increasing its pressure. When utilized in the steam engine, superheated steam possesses the following advantages:

1. The more heat supplied per unit of volume of steam to the engine, the more work can be obtained from the engine, and the increase of pressure having a practical limit, this extra heat is to be obtained by superheating the steam. A moderate amount of superheat produces a large increase in volume, the pressure remaining constant and diminishing the weight of steam per stroke for a given amount of work.

2. The diminished density of the steam employed to do the work lessens the back pressure, or, as commonly expressed, improves the vacuum. This also applies to the air and vapor which are carried with the steam, and further expanded by the increased heat, and are consequently contracted to a much less volume when chilled, by striking the cooling surface of the condenser; thus the air pump has less work to do.

3. The prevention of condensation during expansion without the use of steam jackets is the most important advantage to be attached to the use of superheated steam. Steam jackets are wasteful and inefficient when applying heat to the engine. Inefficient, because the contact is only with the steam immediately adjacent to the walls of the cylinder, with probably little effect being derived by the steam in contact with the piston and in the interior of the cylinder out of reach of the radiation from the walls; wasteful, because of the full effect of heating the exhaust steam after it has done its work in the cylinder during the waning stages of expansion and throughout the exhausting stroke. This is particularly true of engines which have a pause at the end of the stroke, which pause always finds the cylinder full of steam which has completed its work in the cylinder and is ready to be exhausted. Ample evidence of the truth of this statement is found in the high ratio of water condensed in the packets of direct-acting pumping engines to the amount of steam used in the cylinders.

4. Elimination of condensed water in piping leading to engine.

5. Reduction of friction, cutting down loss of pressure in ports and passages, and permitting reduction in size of conducting pipes.

Factors Governing Advisability of Using Superheated Steam

The decision to use or not to use superheated steam in any particular plant will depend upon a thorough study of the plant conditions, taking into account fuel cost, engine performance, capacity of plant, steam line losses, cost to install and maintain superheaters, etc.

Engine Performance: As a general proposition, the savings to be effected from the use of superheated steam vary inversely with regard to the efficiency of the prime mover when using superheated steam—being greatest with direct-acting pumps, and smallest with steam turbines. A fair estimate of the average saving which may be effected with moderate superheat, that is, say 100 to 125 degrees F., based on continuous operation of existing plants, is for slow-running full-stroke, throttling engines, including direct-acting pumps, 40 per cent.; simple engines, non-condensing, with medium piston speed, including compound direct-acting pumps, 20 per cent. for compound condensing Corliss engines, 10 per cent.; for triple expansion engines, and turbines, 6 per cent. Of course, higher figures than these have been obtained but these may be taken as a fair average. Table 1, below, gives a fairly accurate range in steam consumption for prime movers, based on saturated steam, 100 degrees, and superheated 200 degrees.

TABLE I.

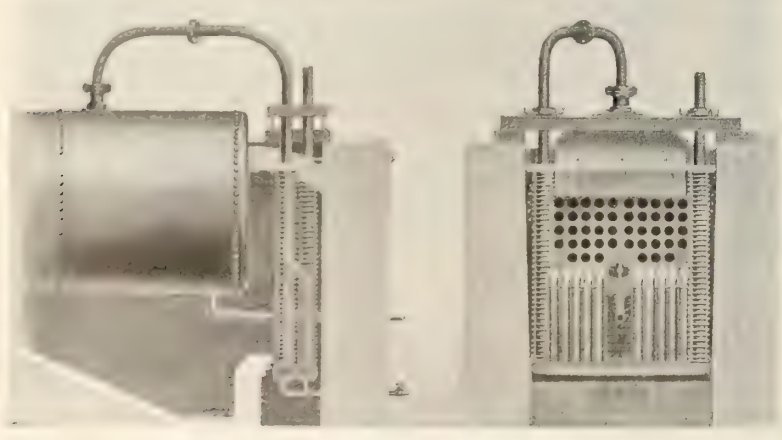
Ranges in Steam Consumption by Prime Movers.

Type Engine	Steam Consumption, lb. per H.P. Hr. Saturated Steam	100° Superheat	200° Superheat
Simple non-condensing ..	29-45	20-38	18-35
Simple non-condensing automatic	26-40	18-34	16-30
Simple non-condensing Corliss	26-35	18-30	.....
Compound non-condensing	19-28	15-25	13-22
Compound condensing ..	12-32	10-20	9-17
Simple duplex steam pumps	120-300	80-160	.....
Turbines non-condensing (kw. hr.)	28-60	24-54	21-48
Turbines condensing (kw. hr.)	12-42	10-38	9-34

Capacity of Plant: Naturally, the capacity of the plant has an important bearing upon the advisability of using superheated steam, inasmuch as the cost of the installation may be out of proportion to the savings to be effected. If the steam consumption is equivalent to about 250 h.p. continuously, however, it would seem desirable to investigate the possibilities of superheated steam.

If the plant is large, the question should, by all means, be taken under advisement. This is particularly true where there is any apparent lack of boiler capacity, as it may develop that the use of superheated steam will necessitate the purchase of additional boilers.

Another point worth remembering, in this connection, is that in the case of old boilers, where the insurance companies may require that, owing to their condi-

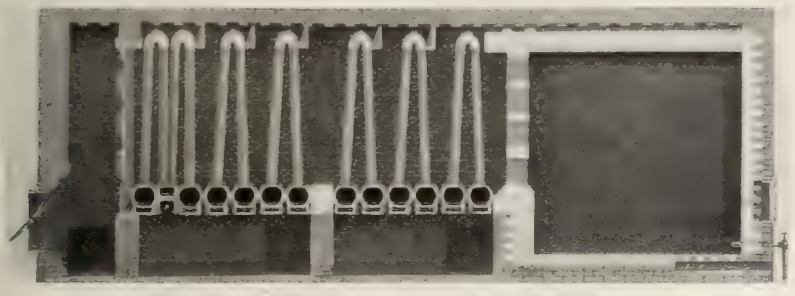


SUPERHEATER ON HORIZONTAL WATER-TUBE BOILER.

tion, they be operated at lower pressures. Under such circumstances, a loss in capacity of the boiler results. This loss may be made up by a change from saturated to superheated steam.

Steam Line Losses: Condensation in long pipe lines is a problem which is faced in many plants. Ninety per cent. of the heat necessary to evaporate water is latent heat and if condensation takes place before the steam is transformed, this latent heat is liberated and the waste and losses, due to condensation may be very large. Under the best conditions, with properly proportioned, well-covered steam pipe, we find a loss of 1/5 to 1/3 of a degree F. of superheat per foot of steam pipe. It seems reasonable to assume that with the ordinary large and indifferently covered steam pipe, that the loss may reach as much as one degree F. for every foot of pipe; consequently, a pipe 100 feet long would probably lose 100 degrees of superheat which is equivalent to five per cent. of moisture in the steam, if we assume that the steam is dry before leaving the boiler.

Superheat is necessary to raise the temperature of the steam to a point where it may all be transmitted to its destination without continuous loss. As superheated steam does not give up its heat as readily as saturated steam, it can be transmitted with smaller total loss. Superheated steam is, therefore, fore, valuable as a means of eliminating the condensation in steam pipes.



INDEPENDENT TYPE OF SUPERHEATER.

Cost of Installing and Maintaining Superheaters

The cost of installing superheaters should be figured to include not only the cost of the equipment, but also the cost of remodeling the steam lines, should this be necessary. Superheated steam will, of course, cause greater expansion and contraction in the steam lines, and it may be necessary to make important changes in these lines before superheated steam can be used.

Insofar as maintenance is concerned, if the superheater is installed in the boiler, it can be regarded as a part of the boiler and there is no reason why this maintenance should be higher than that of the boiler with respect to the comparative cost of the two installations. If pipe lines are not properly arranged, they may be more expensive to maintain, but the remedy for this is proper arrangement to take care of the expansion and contraction. Once this has been secured, there is no reason why piping for superheated steam should cost more than that for saturated steam.

Degree of Superheat: In the United States and Canada, total steam temperatures rarely exceed 600 degrees, while in Europe 600 degrees is a common temperature, and temperatures of 850 degrees are often reached. This does not necessarily mean that steam practice in Europe is in advance of steam practice in America and Canada. In Europe they have had a condition of excessively high fuel costs and low labor costs, whereas we have had the reverse, that is comparatively cheap fuel and very high costs for labor and materials. This means that, insofar as we are concerned, the greatly increased cost of an installation above a total temperature of 600 degrees F., may so far offset the possible savings in fuel that the installation will not be economical.

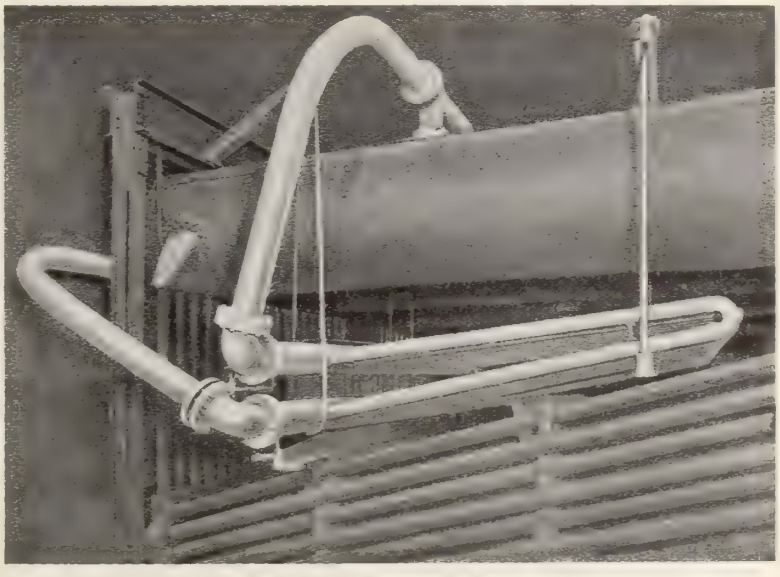
As a general proposition, we may state that for at least ninety-five per cent. of the steam plants in the United States and Canada, 100 degrees of superheated steam is about right, and that only in exceptional cases should superheat exceed 125 degrees.

It should be remembered that high temperatures are apt to interfere with lubrication, and perhaps to cause warping of the valves. With superheat, difficulties of this nature are to be expected. While on this subject of the effect of superheated steam on the valves of an engine, it may be well to run over conditions obtaining in the engine when superheated steam is used. After leaving the superheater and while passing through the steam lines, the heat lost by radiation does not cause condensation, but instead merely causes a loss of a portion of the superheat.

The greatest saving from superheat is obtained in the engine cylinder and results from the elimination of most, if not all, of the loss due to cylinder condensation. The saturated steam losses ordinarily occur in the cylinder, due to condensation caused by the steam coming in contact with the relatively cool cylinder walls. The drop in pressure, caused by this condensation, induces a further flow of steam into the cylinder to fill the space originally occupied by the steam which has been condensed. In the average simple engine cylinder, condensation varies from 20 to 40 per cent., and as water condensation takes up only 1-150 as much space as the steam, we may assume that the same amount of steam will be required to replace that which has been condensed. Even with superheated steam, we do not always obtain dry steam at cut-off, but the important point is that most of the losses caused by cylinder condensation are eliminated. The presence of moisture in steam is apt to result in the use of large amounts of oil for lubricating purposes, and water in the steam tends to wash all water out of the oil. With superheated steam, the walls of the engine cylinder are free from water. A thin film of oil adhering to the surface will give perfect lubrication.

Superheater Construction

Superheaters are of two general types; those placed independently of the boiler, and those built into the boiler and at some point heated by the gases from the boiler furnaces. With water-tube boilers,



SUPERHEATER ON HORIZONTAL RETURN TUBULAR BOILER.

it is usual to place superheaters between the first and second passes, although this arrangement varies with the individual boiler. With fire-tube boilers, the superheater is placed in the combustion chamber at the rear of the boiler.

Since the absorption of the heat depends upon the average differences between the gases and the steam, the required degree of superheat may be obtained from a comparatively small amount of heating surface close to the furnace, or a larger amount at a greater distance.

The requirements of a successful superheater are:

1.—Safety of operation and minimum danger of overheating.

2.—Construction permitting of free expansion.

3.—Arrangement such that it may be cut out without interfering with plant operation.

4.—Provision for keeping surfaces exposed to gases free of soot.

Advantages of the independent superheaters are:

1.—Degree of superheat is not dependent upon boiler performance.

2.—Repairs may be made without reference to the boilers.

Among the disadvantages are:

1.—Requires individual attention.

2.—Requires extra piping.

3.—Requires additional space.

Among the advantages of the superheater placed in the boiler setting:

1.—Lower first cost.

2.—Requires no individual attention.

3.—Takes up no additional space.

Among the disadvantages are:

1.—Subject to boiler conditions and must frequently be watched during the period of cutting in boilers, and superheat is apt to fluctuate with temperatures in the furnace.

A great deal has been written about the advantages and disadvantages of certain types of superheater construction. At the present time there are a number of superheaters on the market which have been brought up to a high state of perfection and there is no need here to enter into a discussion of their relative merits. The commercial superheater companies and large manufacturers of superheaters have competent engineers who specialize in superheater work, and the power plant manager or superintendent contemplating a superheater installation will do well to consult with these specialists.

Materials for Use for Superheater Steam

Where boiler pressures are high and a comparatively high degree of heat is used, it is necessary to pay special attention to the materials and construction of the piping system. The following points are worthy of note in this connection:

Piping: Screw joints are not generally desirable with superheated steam. This makes necessary the use of welded flange, Van Stone, or similar joints. For this work, piping made from open-hearth steel is more desirable than ordinary wrought iron piping, because it can be properly worked since it contains less carbon, and the quality is more uniform.

Fittings: Fittings are now manufactured especially for superheated steam, and for this purpose are entirely satisfactory. A point to be watched is that the fittings as purchased from the manufacturers are specified as being intended for use with superheated steam. Of course, as a matter of good practice, it is well to limit the number of fittings as much as possible by the use of welded joints and bends in the pipe.

Valves: The very best valve obtainable should be used for superheated steam. There is a general impression among the engineers that globe valves and angle valves are more apt to prove steam dry after a period of use than gate valves, although the gate valve has the advantage of causing a much smaller drop in pressure, due to its design permitting a straight flow of steam. A piece of steel six inches long when heated to 500 degrees F. will expand .019 inches. This fact shows the variations in the co-efficient of expansion of the metals of which they are constructed will have an important effect on the performance of a valve setting tight. Valve setting is a point which should be watched.

Metals: Various authorities state that cast iron should not be used at temperatures which they variously state as ranging from 480 to 575 degrees F. Above this temperature, the limit of elasticity in cast iron is reached, with a pressure ranging from 150 to 175 lbs. Under such conditions the material is strained and does not resume its former shape, eventually showing surface cracks which continue to grow until the metal parts. From this, it follows that castings are not suitable for either fittings or valves in superheated steam work. Cast steel is, undoubtedly, the best material for both valves and fittings. This metal is capable of withstanding all temperatures and pressures up to at least 800 degrees F. without showing any appreciable weakness.

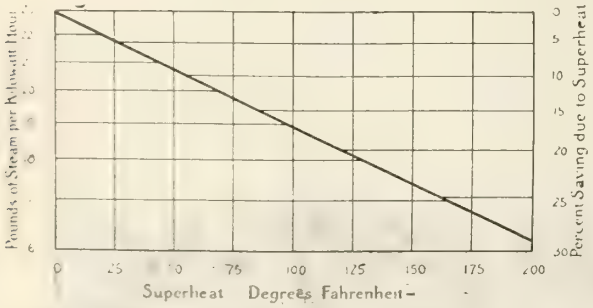
High temperatures have a very pronounced effect upon the breaking strength of brass and bronze, and these materials should not be used with superheated steam as they will soon get out of shape and eventually break.

Gaskets: Copper or bronze gaskets are looked askance upon by many engineers for superheated steam work. Among types which met with favor are corrugated soft Swedish steel gaskets and corrugated or bronze gaskets surrounding asbestos.

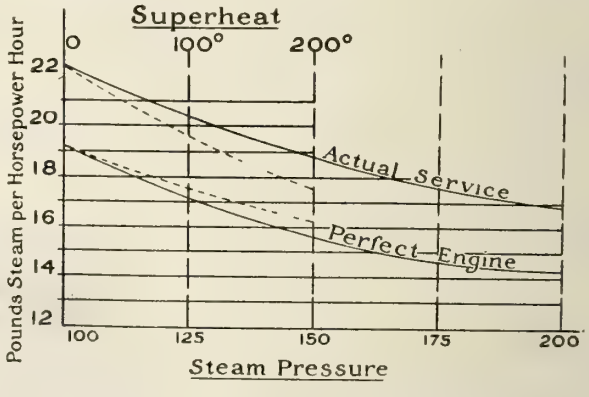
Operating Notes

There are times when, in the ordinary use of a superheater, the circulation of steam will be less than at others. While at such times superheaters may be exposed to the furnace gases at high temperature, such a condition occurs when the load is temporarily arrested or when cutting in the boilers to guard against damage. Under such conditions some superheaters are provided with flooding arrangements by which superheater types are filled with water and this made part of the evaporating surface of the boiler. To do this, it is necessary to open and close certain valves on each boiler, an operation which must be reversed when the critical period is over and the superheaters are to resume their normal practice.

Admitting water to the interior of the superheater induces a formation of scale to the tubes. Moreover, a superheater which has been flooded must be drained before being put back into service. This necessitates, on each boiler, a double operation on the part of the attendant which must be carried out with great care and intelligence, because of the disastrous results to the engine which might follow if the water in the super-



SAVING DUE TO SUPERHEAT-TEST OF HIGH-SPEED TRIPLE EXPANSION ENGINE—BELLIS AND MARCOM LTD., BIRMINGHAM. 100° SUPERHEAT REDUCES STEAM CONSUMPTION PER K.W. HOUR FROM 23 POUNDS TO 18.8 POUNDS—SAVING 17 PER CENT.



EFFECT OF INCREASING SUPERHEAT (DOTTED LINES) FOR PERFECT ENGINE AND ACTUAL SERVICE.

Electric Power Collection From Small Water Power Developments

By C. P. STEINMETZ

In the development of the arts and sciences, and especially in industries which have advanced as rapidly as electrical engineering, we frequently strike barriers which seem to stop further progress in a certain direction and give the impression that the possibilities have been exhausted and the final limit reached in this direction, until some new idea carries us beyond or around the apparently unsurmountable barrier and the beyond shows us a field of development vastly greater even than what had before been considered as the final possibilities. Or more often it is an old idea, which though discarded in the earlier days of development, leads us beyond the barrier which had stopped progress. Thus, when we see development slow down and apparently the limit of progress reached in certain directions, it is advisable to go back to the earlier days and search whether, amongst the ideas then unsuccessfully tried, we may not find some which lead to success under the changed conditions.

A good illustration is given by the history of electric lighting. Metal filaments were tried but found wanting in the earlier days, before the carbon filament, and for a quarter of a century the latter held sway. But after the first few years of rapid advance, progress slowed down and apparently the ultimate limit had been reached at about three watts per mean spherical candlepower. Then the old idea of the metal filament, backed by the twenty years' advance of chemical engineering, carried us around the barrier and more than quadrupled the efficiency of incandescent lighting.

So power generation by the reciprocating steam engine seemed to approach a limit in size and economy of units, until the development of the oldest type of steam engine, the steam turbine, carried us far beyond the possibilities of the reciprocating steam engine.

So the interpole or the commutating pole had been known for many years, but lay dormant until with the change of conditions of commutating machine design it became the means of advance beyond the barriers which were limiting further progress.

But if ever progress was important, and especially engineering progress, beyond the barriers retarding the advance, it is now, in our present period of the world's reconstruction.

But to progress beyond barriers, we first have to see and realize those barriers, and long familiarity with existing methods of doing things tends to standardize our thoughts and leads us to consider as essential and inherent, features which are only incidental and due to the conditions under which the development has taken place, and disables us, when these conditions change, to see beyond the incidental limitations. Standardization is useful and important, and indeed industrial progress would be impossible in the chaos which would result without standardization, but standardization becomes harmful when extending to our thoughts whether and how things can be accomplished. One of the first ways to realize and overcome this limitation is to review the development and ask ourselves why it has taken place in that partcular direction, how far the course of development has been due to temporary conditions and whether with the change of these conditions a different direction of development may lead us beyond the possibilities of our present achievements.

Let us apply this to the development of electrical machinery.

The electric generator and the electric motor are identical. Often the same machine is used as generator or as motor, and where there are differences in construction, they are in details, to accentuate certain characteristics for certain purposes.

Thus in a synchronous machine we may add a squirrel-cage winding in the field pole shoes, when used as a synchronous motor, to give a better starting torque, while we may omit this winding in the generator; but the turbo-alternator when left in circuit, with the steam cut off the turbine, continues to revolve and is just as good a synchronous motor; in a commutating machine we may add a series field when intended as a generator, to give better voltage regulation, and omit it in the use as motor, since the speed regulation of the shunt motor is sufficiently close, etc.

Quarter Century Development

Looking back over the electrical development of the last quarter of a century, we have seen the size of generators and generating stations steadily increase, due to the higher economy of larger generators and generating stations. The maximum size of motors also has steadily increased up to units of many thousand horse-power; but the average size of motors has increased little, if at all, due to the increasing use of individual motors, applied directly to the driven machines.

The average motor is installed with a switch to turn it on, and a fuse to cut it off in case of overload or accident, and then left to itself with practically no attention. In the generator installation, however, we find a very elaborate system of switchboards, instruments, controlling and protective devices, etc., requiring continuous and highly skilled attention. Why is this, if generator and motor are the same type of apparatus? Obviously, it is not due to the use of the machine, in the one case as motor, in the other case as generator, but it is due to the size of the machine. With the huge size of the average generator installation, an elaborate system of control and protection becomes necessary, which is not necessary with the average small motor installation, and indeed, in the installation of very large motors, we find more controlling and protective devices than a switch and a fuse.

Thus, inherently, a generator installation is no more complex than a motor installation. The complexity of the modern generator installation is the neecssary result of its huge size, and a small generator installation could be as simple, limited to switch and fuse as controlling and protective devices, could be left to run itself with occasional ininstallation has steadily increased, while the average size of motor has not, this is not due to the complexity required in the former, but the reverse is the case, the complexity of the generator installation is the result of its huge size.

The difference in the course of development of motor and generator thus must be found in other directions. As an instance, let us consider the application of the electric drive to the cotton mill industry, which is typical of the entire electric motor development.

When the first cotton mill was electrified in 1894, the steam engine was taken out, and a 400-horse-power synchronous motor put into its place, driving by belts and shafts and countershafts the individual machines; that is, the power was generated electrically, but distributed mechanically. But in the new mill of the same plant, a number of 100-horse-power induction motors were installed, each driving a line of shafting to which the individual machines were belted; that is, at least a part of the power distribution was done electrically. I need not say that even this is antiquated and that experience has long proven that the most economical arrangement is to entirely eliminate mechanical power distribution and distribute all the power electrically, up to the individually driven machine. That is, to have individual motors at every machine. This has long become the standard method of electric motor application. This is the reason why the average size of electric motor is small, corresponding to the power required by the individual machine, and large motors are used only where a large unit of mechanical power is required, as at the rolls of a steel mill, or the propeller of the battle cruiser.

But in electric generation we are still in the first stage, that typified by the huge synchronous motor distributing power mechanically through numerous belts, shafts and counter-shafts. We collect the power of a watershed mechanically by elaborate hydraulic works, costing many times more than the most elaborate generating station, and then in a big unit convert the hydraulic—that is, mechanical — power into electric

power in a modern synchronous generating station. Or we burn millions of tons of coal under the steam boilers in our huge steam stations, extract 10 to 14, or possibly 20 per cent. of its energy as electric power, and then pay for the condensing water to throw away the 80-odd remaining per cent. of the heat energy of the fuel, while in numerous other furnaces we burn millions of tons of coal to produce heat, but waste the potential mechanical and electrical energy of this coal.

This is not a condition to make us proud of our industrial efficiency. But it came about naturally, as the result of historical development.

The first electrical development occurred where hydraulic power was available in concentrated form, at waterfalls such as Niagara, etc., that is, cases corresponding in motor development to the rolling mill or the ship's propeller. The synchronous machine is the proper type of generator for such installation, just as the synchronous motor is to-day, and always has been, the preferable type of motor for large units of power unless special conditions prevail and demand the induction motor, such as the need of frequent starting under heavy torque.

The same type of hydro-electric development was extended to conditions where water power was available in less concentrated form, and had to be collected by more extensive hydraulic works, gathering together the power of a watershed, and so the modern hydro-electric generating system was developed as the most perfect known method, within its scope and limits, of utilizing water power — mechanical collection of the water power by hydraulic works, and conversion in a big-unit synchronous generating station.

But the high cost of the hydraulic work makes such development ecenomically feasible only where large amounts of water power are available in fairly concentrated form, and with the increasing development of such power sites, the number of water power capable of development by our present methods is decreasing, while most of the country's potential water powers cannot be developed by our present standard methods of hydro-electric generation, as the cost of the necessary hydraulic development, to collect the water power, is greater than the value of the power which may be collected. The only hope which can be seen for a more complete utilization of our country's hydraulic power, from the abandoned mill sites of New England to the mountain streams of the South and the West, thus lies in applying to the electric generation the same principles which have made the electric motor economically successful; that is, bringing the electric machine to the place of power. That is, just as we place individual motors at every machine where mechanical power is required, and distribute the power to them electrically, so as to place individual electric generators wherever along the water course hydraulic power is available, and collect the power of all these generators electrically.

Small Induction Generator Station

For these relatively small individual generators, required for electric power collection, induction machines would naturally be used just as induction machines are exclusively used for smaller units of motors, however superior the synchronous motor is for larger powers.

Such a small induction generator station then would consist of a standard low voltage induction motor connected to some simple and cheap hydraulic turbine, a few hundred feet of pipe, and a low dam across the creek, to cover the intake of the pipe; a step-up transformer connecting the machine into a medium voltage collecting line, low tension switch and fuse to disconnect in case of accident. Hundreds of such small induction generating stations then would feed into the system over collecting lines, just as hundreds of induction motor installations receive power from it over distribution lines, and a large synchronous main station — steam turbine or hydraulic, or possibly even merely a synchronous motor station — would control the voltage and frequency of the system.

In similar manner, a simple and cheap turbine induction generator plant, interposed between the high pressure steam boiler and the steam heating system which it supplies, would abstract the small percentage of fuel energy which is available in conversion to mechanical and electrical power, and turn it into the electrical distribution system, on whch the induction generator floats, thus collecting electrical energy from numerous small stream stations and eliminating the present wasteful use of coal.

Now this development of electric power collection is coming, as it is the natural economic development of electric generation, just as the individual motor drive was in electrical power distribution. There are already a number of such hydro-electric induction generator installations throughout the country, some in succesful operation for years, and the field thus opened up is very large, larger possibly than all the electrical development which has taken place hitherto, and one of the features of this development is that no new type of apparatus requires to be developed, but the standard induction motor can be used as an induction generator, and has been used successfully for years in some plants.

BEESWAX SAVES MINE PUMPS

The rapidly destructive corrosive effect of acid water in mines is frequently quite astonishing. Pumps have sometimes been rendered absolutely useless in two or three days. Harry Goodman tells in a recent issue of *Coal Age* how a simple, cheap and efficient method of protecting mine pumps from the corrosive action of some particularly bad mine water was recently tried out successfully at Herrin, Ill. After five pumps had been put on the scrap pile one after the other, Elmer Mayor, the top boss, conceived the idea of using beeswax on the parts of the pump exposed to the action off the water. Accordingly, he took apart a new pump, carefully wiped off all grease and dirt from the faces and even from the bolts that clamped the parts together. After carefully heating the clean surfaces he applied the melted beeswax to form an even, thin coating and bolted all the parts together with similarly treated bolts. The pump was then installed and has run without any further attention except the regular oiling. Before the beeswax was tried the pumps lasted from one to three days. The treated pump has been running for several months.

A RECORD IN BRILLIANCE

The most intensely brilliant light in the world is that produced by the flow of electric current between two pencils of carbon. The supremacy of this light —the carbon "arc" lamp, discovered by Humphrey Davy about one hundred years ago—is threatened by a new type of lamp, in which an arc is "struck," as the phase goes, between the minute globules of tungsten in a vacuum bulb similar to that of an ordinary electric lamp. Just before the war British research had produced a lamp of this type with 100 candle power, and the resumption of the investigation after the stress of war has enabled a means to be discovered of producing larger globules, so that lamps of much higher candle-power have been made. At an early date, one with 4,000 candle-power will make its appearance. As the source of light is practically a point, the lamp is very suitable for kinematograph work and for various microscopic and surgical purposes. Being rich in the actinic rays which act on sensitive plates, it has also a wide scope in photography. Its efficiency is very high, though not quite so high as that of the latest types of arc lamps, and its simplicity, its convenience, its long life, and the absence of flickering in the light are likely to make this British invention very popular wherever a concentrated light is required.

A BRITISH SUPER-WINDING ENGINE

An exceptionally powerful winding engine was recently installed in a coal pit in Northumberland, England. It is driven by electricity and is capable of raising 150 tons of coal per hour from a depth of 900 feet. The latest types of electric signalling apparatus have been fitted, along with safety appliances to control the travel of the cage. This large plant, which, in many of its features, is the first of its kind in Northumberland, was designed by the engineer to the coal pit.

Ice skating without ice has been made possible by a New Yorker who has invented skates with a number of rollers set between plates to serve as runners.

Disconnecting Switches and Bus Bar Supports

The Increasing Size of Power Plants Necessitates More Careful Design of Detail Equipment and More Careful Attention to Features Hitherto Neglected. The Following Article Describes One Line of Equipment Manufactured to Meet Exacting Conditions

DELAYS and outages due to short-circuits and switching mistakes have ever been serious, but with increasing sizes in generating units, the significance of better equipment in switches and busbar supports is very apparent to anyone. We now have units of 20,000, 25,000, 30,000 and 35,000 kilowatts, and with 50,000-kilowatt units already designed and being called for by some of the big companies, the bus and switch detail to care for these big units has not progressed with the demand. Consequently, certain large plants have suffered serious losses due to failure of bus supports and their attendant structures and compartments; disconnecting switches have also been opened by shorts and other causes. To provide more reliable and safe devices for these conditions, the engineers have first called for heavier and more rugged bus supports with greater factor of safety, and then called for a locking type of disconnecting switch, followed with a demand that the locks must be positive, and then with further demands that the locks must be foolproof and interferenceproof.

Engineers are to-day demanding better switches with guaranteed minimum millivolt drop under full load, fixed frequency and temperature; such switches can only be manufactured with special care and materials. The use of solid copper forgings has made possible great savings in energy formerly lost through use of poor design and cast copper parts in switch construction. Another waste in energy is found in the various clamp devices that are used on the buses, supporting cables, etc. The elimination of this waste can be obtained by the use of non-magnetic materials in the construction of the clamping member or the supporting device of the conductors.

Phosphor-bronze bolts, when machined from the solid rod, have great strength and are superior to brass or other metals. The porcelain factor is one often neglected by the designing engineer, primarily owing to a multitude of other details seemingly of more importance, It is not generally realized that the entire system is dependent upon the insulating properties and strength of the station porcelain, whether this be on switches or on bus supports. Porcelain manufactured by the wet process has greater strength than that of any other process and is, therefore, used exclusively for all classes of important devices and fittings. Such porcelain can be equipped with well-cushioned mechanical clamps for the proper support of its hardware. The use of cement in any form should be avoided. The design should permit a test with combined high frequency and high potential of, say, four to seven and one-half times greater than the service voltage, and on high-capacity service, due allowance must be made for "spill-over" troubles. This usually requires very heavy and rugged porcelain.

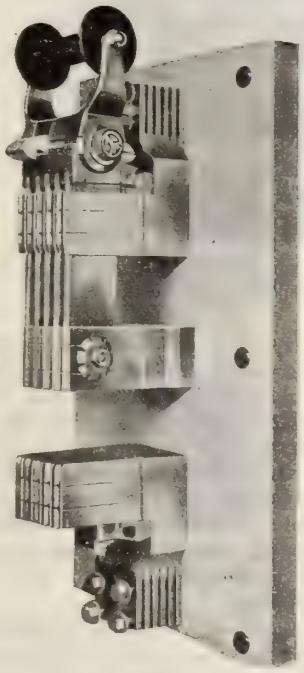


FIG. 1—5,000-AMPERE SWITCH.

The General Devices & Fittings Company, Chicago, Ill., has recently furnished much switch and bus-support equipment for three of the largest power plants in the country, and descriptions and illustrations of a few of these new designs are given here for the first time.

Fig. 1 shows a front view of a back-connected positive-lock type switch with a rating (on the conservative basis of 680 amperes per square inch of cross-sectional area and of 68 amperes per square inch of contact area) of 5,000 amperes and 600 volts, 60 cycles, and 20 degrees Fahrenheit limit temperature rise. These are the only switches ever provided with a positive lock which is thrown in or out with the switch handle. The studs are milled from solid copper forgings and slotted seven inches deep for bus insertions. The studs can also be slotted for flat connections. All contacts are ground to reduce the millivolt drop to the lowest possible point. All hardware, bolts, nuts, spring washers, etc., are of phosphor bronze, turned from solid rod. The clips are of Sigamond spring copper; the blades are extra-hard-drawn pure blading copper; the handle fork and entire lock are of Hertz non-magnetic metal; and the handle itself is of black fibre made from rings turned to size and treated. This

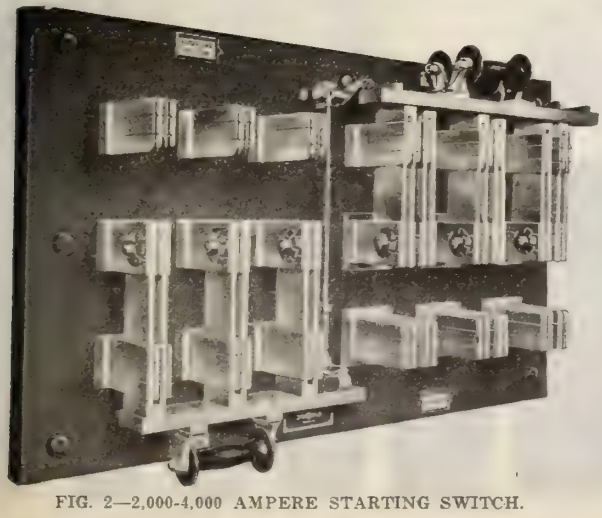

FIG. 2—2,000-4,000 AMPERE STARTING SWITCH.

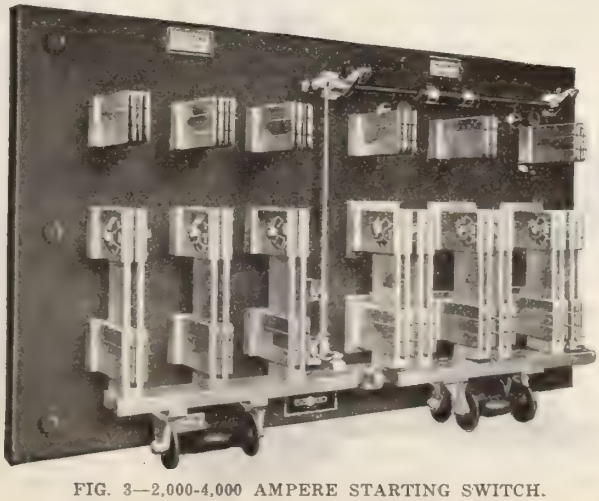

FIG. 3—2,000-4,000 AMPERE STARTING SWITCH.

switch is made in sizes up to 16,000 amperes; above 10,000 amperes all sizes are equipped with double-cushion locks and interferences.

Figs. 2 and 3 illustrate a convertor starting switch of 4,000 ampere capacity at 600 volts. One feature of particular interest on this switch is the interlocking mechanism. This holds the running switch from closing until the starting switch has passed through two starting steps. It also holds the running switch in position clear for starting. The studs and laminated terminals and clip blocks of this switch are of pure copper forged in one piece. Clips are of Sigamond spring copper with ground contact surface. Blades of pure hard-drawn copper machined and brushed finish.

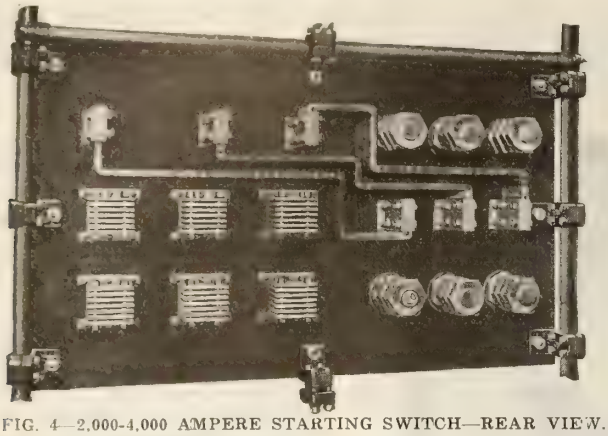

FIG. 4—2,000-4,000 AMPERE STARTING SWITCH—REAR VIEW.

Rear view of this switch is shown in Fig. 4. The switch, complete with its marble mounting, weighs approximately one ton.

Fig. 5 shows a special extra-heavy switch for 2,000 amperes and 15,000 volts, equipped with positive snap lock and vertical terminals for bus insertion. The patent bridge base is an assurance for front-connected switches and horizontal only, if the switches are back-connected.

Fig. 6 shows a special double throw disconnecting switch, for use in conjunction with type H oil switches. The switch is arranged for flat mounting, and the locking arrangement provides for locking the switch either on to the oil switch terminal or on to the alternative connection.

Fig. 7 illustrates a few standard wall bushings for round conductors insulated for 15,000 volts.

A special three-phase bus support for 600-volt service is shown in Fig. 8. All metal, except in the bases, is Hertz non-magnetic metal; the bolts are phosphor bronze, machined from solid rod. These supports are now made in all sizes and voltages and to support up to 19 bars one-fourth inch by ten inches, which, so far as known, is the largest support ever made of this type. Any combination of mounting can be arranged for. This support is also adjustable. Its weight is 320 pounds.

Fig. 9 shows a 66,000-volt special extra-heavy contact-type bus support for holding heavy vertical buses, and arranged to be mounted in and between a 36-inch compartment.

Fig. 10 is a heavy double support for large horizontal bus bar, insulated for 13,200 volts. It is arranged for flat mounting in standard concrete compartments, and provision is made for vertical adjustment of the bar.

Fig. 11 illustrates a line of cable clamp supports for pipe mounting and for use on single, two, three and five-wire runs. Cable clamp support has a malleable iron base, and when used for A.C., the cover is a bronze casting. Both top and bottom sections are extremely heavy design with heavy webbed flanges.

Fig. 12 shows a heavy contact-type bus support for 15,000-volt service. This support is adjustable all round. All porcelain is tested with high frequency at 220 to 280,000 cycles and is also given a combined high-potential, 60-cycle, and high-frequency test of 275,000 cycles before shipping, and this test is with all hardware and equipment in place. All shipments are packed in cartons, each unit being entirely complete.

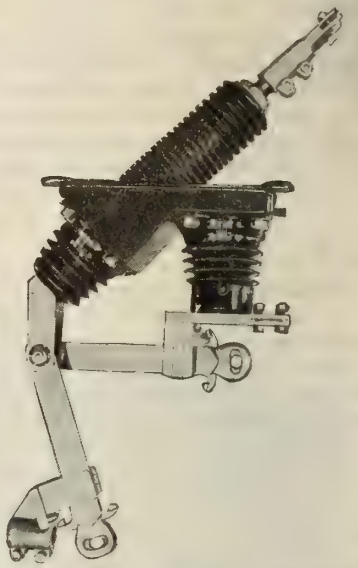

FIG. 6—SPECIAL OIL SWITCH, DISCONNECTING SWITCH.

The General Devices & Fittings Company was the first manufacturer to build switches with a guaranteed millivolt drop, and on both the heavy-capacity and the central-station standards. Copper forgings are used entirely for all switch work and terminals. The porcelain used is said to have no equal for design or strength, and is guaranteed to be wet-process entirely. Corrugated-post types for voltages up to 66,000 volts are stocked. Floor and wall tubes and bushings are also stocked up to 35,000 volts and can be furnished up to 150,000 volts. The

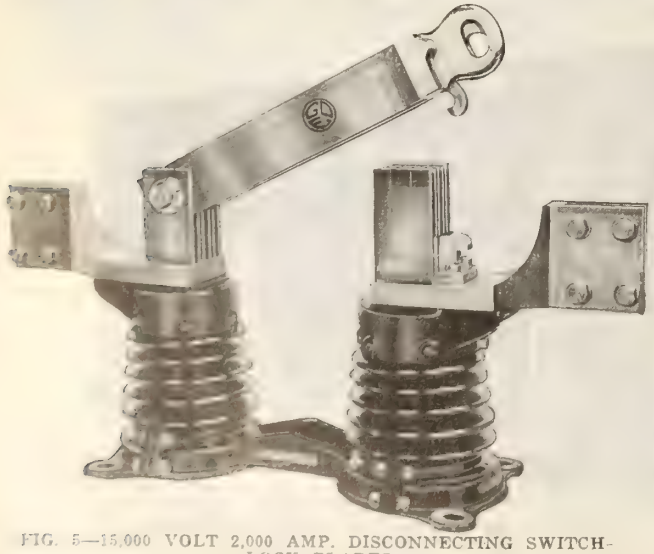

FIG. 5—15,000 VOLT 2,000 AMP. DISCONNECTING SWITCH-LOCK BLADES.

FIG. 7—WALL BUSHINGS. 13,200 VOLT TYPE.

company's exhibit of porcelain is the largest in the country outside of an insulator factory. Its trade-mark "G. D. F." means "Good Designs First", and, taken with its slogan of "Quality and Service", is surely exemplified by the illustrations that are shown with this article.

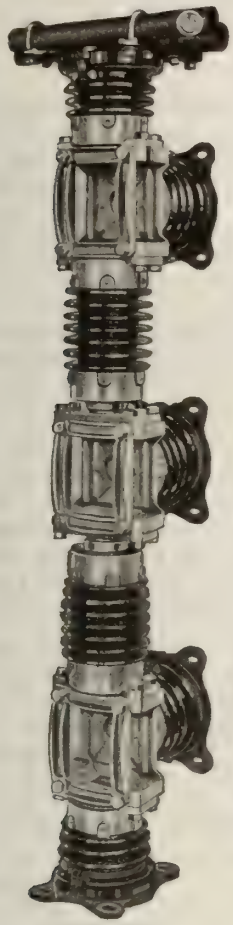

FIG. 8—THREE-PHASE BUS SUPPORT.

One of the interesting features in connection with the manufacturing of this line, is the system of cataloging adopted. It may readily be imagined that the large number of separate devices necessary to take care of modern plant design runs into many thousands, and since many of the parts entering into the complete design of any unit are interchangeable, it is a task of no small difficulty to find a system at once easy to use and accurate. This difficulty has been overcome by the use of a neomonic catalogue, in which each device is given a number formed from the individual part numbers of the different units entering into its construction. This system, together with a designation which defines the type, whether for light, medium or heavy work, serves to identify any one of the many thousands of combinations possible.

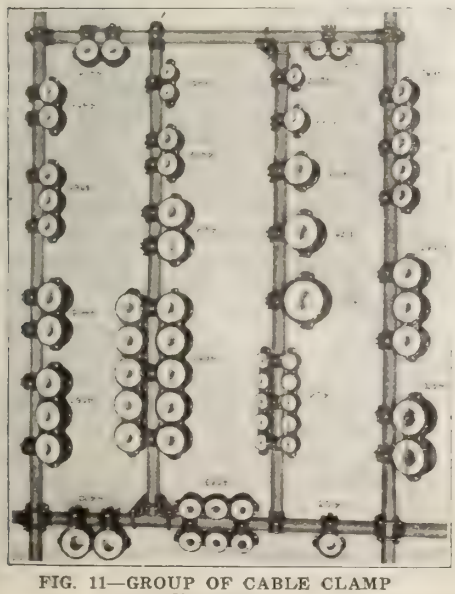

FIG. 11—GROUP OF CABLE CLAMP SUPPORTS.

FIG. 9—6600 VOLT CONTACT TYPE BUS SUPPORT.

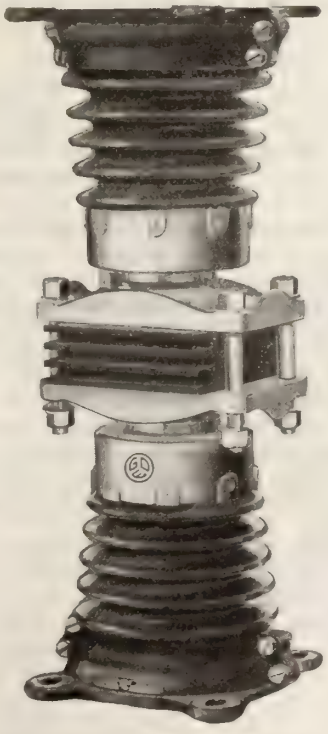

FIG. 10—HEAVY DOUBLE SUPPORT FOR LARGE BUS BAR, 15,000 VOLT.

FIG. 12—HEAVY-CONTACT TYPE BUS SUPPORT FOR 15,000 VOLT SERVICE.

The revival of the project to deepen the St. Lawrence for the passage of ocean vessels is again to the fore, and the possibility has created considerable adverse feeling among New York and American shipping men. The statement of J. S. Duthrie, of the MacDonald Lumber Company, who has been a consistent supporter of the St. Lawrence Canal scheme, emphasizes the advantages of such an undertaking, and says in part: "Ocean vessels will be unloading in the ports even of Lake Superior within ten years. The only thing that will delay it is the fact that the Government has taken over the G.T.R. and tied up the finances of the country for the time being, but that will soon be past. The people of New York see the real facts of the case." S. A. Thompson, the secretary of the Convention of National Rivers and Harbors Congress, expresses the mind of the Eastern section of the States in the following remarks: "Like all the rest of us, the people of New York and the Eastern States want all the business they can get, and because they think, with good reason, that a thirty-foot channel down the St. Lawrence could not only benefit Montreal, but take a great amount of business away from New York, they are violently opposed to the United States Government taking any part in the project."

For several months past the city of Montreal has been experimenting with the use of fuel oil at the Low-Level Pumping Station. Three boilers have been equipped with oil-burning apparatus, but it has been found necessary to revert back to coal firing on two of these, the other remaining as an oil unit, while further tests are being made. So far, the oil method has not proved successful, and the city has assured itself of constant water service by laying in a full supply of coal for winter requirements. A year's supply for this station is in the neighborhood of 56,000 tons.

Laying Out Boiler and Engine Foundations

The Laying Out of the Foundation Has Been Described in Preceding Articles. Mixing and Pouring of the Concrete Are Here Described. Various Features in Which Care Should be Exercised Are Pointed Out

By T. H. FENNER

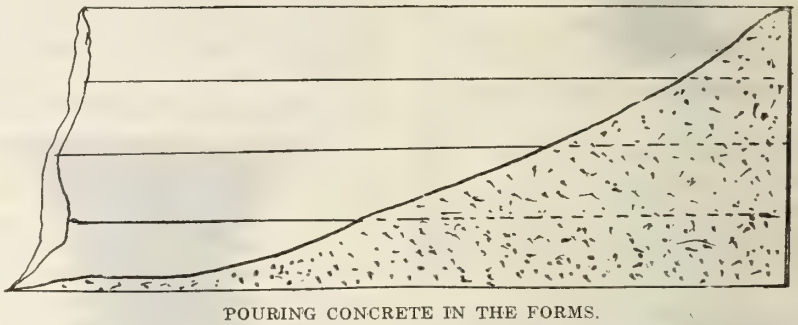
BEFORE mixing and pouring the concrete in making a foundation, take a look round the forms and see that everything is braced and stayed firmly. It is also as well to check up the forms with the foundation plan as a slight mistake can be corrected without much trouble at this stage, whereas after the concrete has set it is an expensive proposition to make alterations.

Arrange for a steady water supply, the best means being a barrel, into which a hose can be led. The barrel can thus be kept always full and the water dipped out with a pail, which is more convenient than using the hose direct. Get the board as near the work as possible to eliminate unnecessary wheeling and save time. Get the men apportioned to their various jobs so that each knows what to do. Obviously at the start of the job the mixing is going to take longer than any other part. Get enough men on the board to handle the stuff expeditiously without being in each other's way. Eight men can work comfortably on an eight foot board, two at each side. To bring the sand and stone to the board will take three men, and it will need three to four men to wheel the mixture to the form and puddle it well after pouring. If there are not enough men available, use smaller batches. With the number mentioned here, a batch would be a barrow load of cement and the sand and stone in the proportion mentioned. Each batch should be thoroughly turned over on the board at least twice, till it is thoroughly mixed. Before pouring the first concrete mix some pure cement and sand and drop it in the bottom of the form to fill up any inequalities in the ground and to provide a bed for the first concrete. In the actual filling of the form it is well to fill the form nearly to the top as the job goes along. This leaves a long slope in the concrete as shown in the sketch, which makes a convenient scarf to join one batch to the next. One of the most important things to be observed in filling concrete forms is to make sure that the concrete will be a homogeneous, water-tight mass when finished. In order to achieve this, every shovelful of concrete should be well puddled as it is poured in the form. By puddling is meant agitating so that there are no empty spaces left between stone and cement. The sure proof of success in this is to see the water rising to the top of the mass, which will occur as the concrete settles closely together. This water is squeezed out, leaving the cement, sand and stone closely and firmly knit together. The larger the stone that is used the more important it is to puddle properly as there is more likelihood of spaces being left between them than with the smaller size. One started, the job should be kept going as fast as it can be done. It may be necessary to rearrange the men as the job goes on, as for instance, taking away a mixer and adding him to the wheeling force. These details are to be adjusted by the man in charge of the job while he is on the job. Hard and fast rules cannot be laid down, and the only object of these articles is to indicate to the man who may be called upon, the methods of going about the job.

When starting to pour concrete after an interval such as a meal hour, or overnight, mix some stiff cement and sand and pour it on the joint. When leaving at night, and before a meal hour, be sure and leave a rough edge to start on again as it is much easier to make a good joint in this way than if the face is smooth. Don't worry about having to make a start after an interval of two or three days even. The cement will knit all right. Concrete remains green for a considerable time, especially if exposed to the weather.

When filling the form do not carry the concrete right to the top, leave about half an inch or one inch for grouting, which is merely filling in with a cement and sand mixture to make a smooth finish. In the places where the feet of the columns are to come this is absolutely necessary. The columns will be placed and levelled up on distance pieces or wedges, and the grouting run in underneath them to make a solid base. This point should always be observed when making foundations for machinery. The top of the foundation should always be left low to allow of the machinery being levelled.

The foregoing has been written assuming that there have been enough men to carry the job right through from start to finish. Of course, if the number of men is limited, the method pointed out in a previous article of carrying on the excavating alternately with the pouring will be the best. This, as already mentioned, economises on cost of forms and labor, and is a very good way of doing the job. However, the pouring will be carried on in the same way, and the same rules applied, whether the job is poured all at once or in relays. Once the form is filled the concrete must be left to harden. It will be about 48 hours before the forms can be removed, or perhaps 72 hours. It is easy to tell by removing a top board if it will be safe to remove the whole thing. If the board comes away easily, leaving the concrete smooth and clean beneath it, the foundation is set sufficiently to allow of the forms being moved. If the board brings away part of the surface of the concrete with it, and is sticky and hard to pry off, leave the form on a while longer. Meanwhile, while the cement is hardening, the ground can be cleared for the bricklaying. The sand left over can be used by the bricklayers. The stone can be moved out to where it may be required later. The steel supporting columns can be brought in, likewise the suspending girders and bolts. Collect all the good wooden blocking 12 inches square, 8 inches and 4 inches that may be needed, and generally utilize the time at your disposal to get everything in readiness for the bringing in and erection of the boiler. Here is where the man has a chance of showing his mechanical foresight and ability. In his mind's eye he must visualize the passage of the boilers from the railroad car or the ground outside, till they are held up on their own suspension brackets ready for the brickwork. It is according to his ability to forecast requirements that the ease and speed of doing the job depends. If ten or twelve men have to stand around a few times a day while some of their number look for blocking, or a jack, or a bolt, or any of the dozen things sometimes wanted in a hurry, the erection will be expensive.. Of course it is not humanly possible to foresee everything, but it is possible to come very near to doing so. The ability to look ahead is a great asset to an erecting engineer. Of course, as in every other line, experience is the great teacher, but every one has to do his first job sometime.



POURING CONCRETE IN THE FORMS.

SOME NOTES ON THE UTILIZATION OF LIGNITE TO THE BEST ADVANTAGE

IN carbonizing the lignite valuable by-products in the form of gas, ammonia, and oils and tar are obtained.

The gas yield is upward of 10,000 cubic feet per ton of lignite. The gas has a heating value of 400 to 450 British thermal units per cubic foot.

A little more than one-half of the gas is necessary to carry on the carbonizing process; the balance can be used as a city gas for cooking, or for lighting if burned in a mantle, for furnace fuel, or for generating power by means of a gas engine. Or, if desired, the entire 10,000 cubic feet can be devoted to these purposes and the carbonizing carried on with lignite producer gas from a fuel gas producer, states a recent publication of the U. S. Bureau of Mines.

If the gas should be used as a town gas, and a higher thermal value than 400 B.t.u. per cubic foot were required, the whole 10,000 cubic feet can be enriched to the desired point. The Director of the Oil Division of the Fuel Administration has proposed that the heating values of carbureted water gas sold for domestic use shall not be over 528 B.t.u. per cubic foot. Or, in a carbonizing oven of the Saskatchewan type, the poorer portion of the gas could be collected separately and only the richer portion, about 7,000 cubic feet, sent into the city mains without enriching. The inferior gas would not be wasted but could be used as bench fuel, supplemented by producer gas. If it were desirable to do the carbonizing exclusively with the oven gas, the richer portion available for distribution in city mains would be reduced to between 3,000 and 4,000 cubic feet per ton of lignite.

The fact that the sulphur content of lignite is small is a good feature. There is an almost entire absence of the corrosive acid resulting from the combination of sulphur with water when the lignite is burned. Should the lignite gas be used as a "stone gas" for heating, cooking and illuminating purposes, there will be almost no sulphuretted hydrogen to be removed by means of hydrated oxide of iron purifiers.

Consider the matter of power: Of the yield of 10,000 cubic feet per ton of lignite carbonized, 6,000 cubic feet are required to carry on the process, leaving a surplus, costing nothing, of 4,000 cubic feet, of 400 British thermal units per cubic foot, or a total of 1,600,000 British thermal units. A good gas engine uses about 10,000 B.t.u. per horsepower-hour. This gives 160 horsepower-hours from the surplus gas from each ton of lignite carbonized. This power is comparable in cost with that derived from natural gas. It is fully as cheap as most hydro-electric power.

This cheap power, of course, is limited by the quantity of lignite carbonized. But the first need of the people in northern climates is domestic fuel, hence the demand for these carbonized lignite briquets is very large. As the population and the demand for power increase, the demand for this carbonized fuel will increase apace. If the demand for power in any lignite field should outrun this supply of surplus gas the amount of power can be readily and cheaply augmented by the use of carbonized lignite in power gas producers.

The by-product should at least pay the cost of carbonizing and briqueting, thus affording a first rank fuel in place of one of lowest rank, at no additional cost.

It is not necessary to dwell upon the benefits that would ensue to these lignite sections by thus placing them in possession of a fuel equal to anthracite and a supply of cheap electrical power.

And these remarks apply to one-third of the coal resources of the nation.

The Ammonia

The ammonia is contained in the gas and gas water. It may be recovered as ammonium sulphate, a valuable fertilizer, as anhydrous ammonia, for refrigeration and other commercial purposes, or it may be treated as the source of other nitrogen products, some of which are of vital importance in the manufacture of explosives. As stated above, this and the Mond process are the cheapest sources of these products, but the amount which can be so recovered is limited to the tonnage of coal carbonized or gasified. The manufacturing practices in this connection have long been standardized.

Oils and Tars

Just what is the most profitable disposition to make of the oil and tar products in this country remains to be determined. This is an industry by itself.

The simple distillation products of this oil can be put to many uses—fuel oil for furnaces and internal combustion engines, creosoting oils for the preservation of timber, waterproofing and preserving oils for leather and cotton and other fabrics, tar paper, roofing pitch, etc.

The pitch makes an excellent binder for the briquets, and will go far toward reducing the cost of this item if more valuable uses are not found for it. The anthracene and creosote oils will, without doubt, find a ready market as wood and leather preservatives.

From the several fractions, upon exhaustive distillation and treatment, are derived hundreds of synthetic products in the way of paraffin, acids, antiseptics, photographic chemicals, aniline dyes, perfumes, drugs, preservatives, etc.

From the light oils come benzol, toluol, aniline dyes, photo-chemicals certain drugs, and many other chemical products. From the carbolic and creosote fractions are derived carbolic acid, creosote, picric acid, photo-dyes and chemicals, coloring materials, and numbers of perfumes. The anthracene oils give, among other things, alizarin, a valuable acid used in the production of dyes, and carbolineum, used as a wood preservative. This latter product is analogous and equal in value to the carbolineum derived from European lignite, which, before the war was imported in large quantities and retailed at 65 cents per gallon in barrel lots.

At first, of course, the simple distillation products will be procured and marketed as such, but as opportunity affords, each of these primary by-products will be taken up and synthetic chemical products manufactured. The exact course of this development is a matter to be determined in conjunction with a careful study of the market.

Almost all of these manufactured tar products have heretofore come from Germany. In 1913 the United States imported coal tar products of the value of $11,000,000 at initiating points, and these, when they reached the consumer, probably cost double that amount. Millions of gallons of creosoting oils for preserving timbers have been imported annually. That supplpy is now cut off and the market value of these commodities on this continent greatly enhanced. It is not unreasonable to expect that in the future a large part of this demand for tar products will be supplied from these immense stores of lignite.

Certain Arkansas and Texas lignites are known to be substantially undeveloped cannel coals, containing a large percentage of volatile matter. It is probable that the day will come when we will distil these lignites to recover products similar to the oils now being recovered from the oil shales of Scotland and elsewhere.

Possible Conservation of Petroleum and Natural Gas

The bringing on to the market of the Texas lignite would release large quantities of Texas petroleum and natural gas for other uses, and the conservation of our petroleum resources is a more important matter than the average man appreciates.

Of our original supply of petroleum, 42 barrels per capita have been used, and only 70 barrels per capita remain for the future. About half of the petroleum currently produced is used as fuel for steam raising. The possibilities in the use of petroleum and its products in connection with the navy, airplanes, the merchant marine, automobiles, motor trucks, tractors, etc., are so great and vital that before long it will be looked upon as an inconceivable folly that oil should ever have been used for steam raising, the most glaring economic perversion that this country has ever been guilty of. (Bulletin 102, part 6, U. S. National Museum.)

"The whole mechanical equipment of modern civilization is dependent upon lubricants made from petroleum. Its exhaustion spells commercial chaos or commercial subjugation by the nation or nations that control the future source of supply from which petroleum will be derived." (M. L. Requa.)

Pioneer of Steam Locomotion

IT IS just 116 years ago this February that commercial use of the locomotive had its inception. In 1804, at Pen-y-darren, in South Wales, Richard Trevithick, the pioneer inventor of the locomotive steam engine, demonstrated its practical value on the Merthyr Tydvil Tramway, hauling 20 tons of ore, at that time considered a remarkable feat for transportation of that character. The first achievement in this direction was a pronounced success, although the initial performance was not all that could be desired, as history tells us that Trevithick had apparently built a machine that he could not control, the engine running off the track and being badly wrecked the first day. The supposition is, however, that the accident was due more to his inexperience as an engine-driver than to any fault in engine construction. From that time onward the steam locomotive has made varied but steady progress, but that just rewards are not always meted out to the master minds is adequately illustrated in the later days of Trevithick's career. In 1814, after a period of successful engineering achievement, he entered on an agreement for the construction of engines for mines in Peru, and removed thence in 1816 to supervise their operation. He returned to England in 1827, and the following year petitioned the English Parliament for a reward for his invention, but without success. He died, penniless, at Dartford, on the 22nd of April, 1833, at the age of 62.

Graded Certificates

INFORMATION has been published concerning the Act grading certificates for a sufficient length of time to enable an estimate as to its reception amongst the engineering fraternity. Generally speaking, opinion seems to be favorable to the Act, although some objections are raised to individual portions of the Act and the regulations respecting it.

The point to which the greatest exception is made is perhaps that relating to the qualifications for a first-class certificate, both as regards practical experience and technical knowledge. At first glance the qualifications may seem somewhat severe, but in no other way can the status of stationary engineering be raised so effectively. The first-class certificate should be one well worth while having, and to achieve this, it must be a fairly hard thing to obtain.

When employers of engineering skill learn that the standards set by the Ontario Board are high and demand genuine worth on the part of the engineer, it will be materially to the benefit of the stationary engineer himself. His pay envelope will undoubtedly be fatter and his reputation more in keeping with his worth.

It may be argued that the first-class certificate will only be available to the limited few and that injury will be done to the older men of the present engineering world. This may possibly be true, but a remedy should not necessitate the lowering of the standard but rather a readjustment of the graded plant requirements. This could be done easily by the Board under Order-in-Council as soon as it were found necessary and with the experience gained during the coming year it will be more fitting to discuss this question later on.

It might be well emphasized that although the engineer cannot obtain a first-class certificate on his application form, much depends upon the manner in which his application form has been filled out, whether he obtains a second or third-class certificate. The application blanks have been issued for a definite purpose and this purpose, briefly stated, is to give the engineer every opportunity to obtain the highest grading possible.

Fuel Oil vs. Coal

OCCASIONALLY someone breaks into print and lauds one of these indispensable sources of heat and power very much to the detriment of the other. Extravagant claims are made, and to those not well versed in the subject of fuel burning these opinions carry weight.

These statements, for instance, make the claim that oil fuel is dangerous, produces smoke, causes corrosion and other evils through its sulphur content, and so on ad infinitum. Such statements only work harm to those bringing them forth and the relative merits of the two fuels for various purposes should be recognized.

Cheapness, or more properly speaking, economy in operation, may be the single object aimed at in determining the type of fuel to use, cleanliness another, and a number of other factors go to make up the weight of evidence which throws the balance in favor of one or other type of fuel, and nothing can be predicated beforehand in most cases as to the outcome. Smoke can be made with the one as with the other, and it is usually present in the use of both under similar conditions. The same applies to other operating features, both advantageous and the reverse.

WHAT THINGS ARE DONE IN NAME OF SAFETY!

Devices Grow and Thrive in This Rare Atmosphere—and What Will Be Coming Out Next?

Editor, CANADIAN MACHINERY:—The pursuit of safety methods is laudable. As an ameliorator of industrial conditions it ranks highly, and the literature diffused so liberally by the High Priests of Safety First add greatly to the gayety of the race. However, like many other good things, it can be overdone, and on some of its devotees it reacts in strange fashion. Looking through the pages of a technical magazine recently, we came across a section headed: "Platitudes for Puzzled Practitioners." This was not the exact wording, but it indicates the meaning. After reading of a bright individual who conceived the idea of putting a fixed obstacle on a lever to prevent a sliding piece sliding too far, we were going to try another section, when a spirited sketch attracted our eye. It showed a hand grasping a cold chisel, and another hand poising a hammer as though to strike. There was nothing in this to cause comment, but on both the hammer and chisel were depicted strange protuberances. That on the chisel was arranged near the end, and looked as though some lady mechanic had tied a ruff round its neck to make it look better. The hammer was decorated right on the end of the shaft, and close examination revealed the fact that the excrescence was an ordinary round washer held on with a coach screw. Now for many years we have used a hammer and chisel, but never saw them fitted up in this manner. Therefore, we anxiously read the text, to find out the raison d'être of such a peculiarity.

It appears that a sturdy mechanic grasped his trusty hammer, and prepared to smite the chisel a resounding blow. Alas, the hand that grasped the hammer was a greasy hand, and instead of striking the chisel, the smooth hammer shaft slid through the greasy grip, and smote an unoffending laborer on the apex of the cranium. Nothing daunted, the mechanic grasped the hammer again and this time his hold was so firm, and his aim so true, that the chisel drove through the metal, slipped through the holder's hand, and hit a second workman who happened to be adjacent. This was too much. Safety First was outraged, and the safety expert called in. One glance sufficed, and the remedy was determined on in a twinkling. Simply fasten a large washer on the chisel, above the hand, and a similar one on the hammer, below the hand, and the trick was done. Oh, safety, what things are done in thy name! For the benefit of those who are interested, we offer some further suggestions:—An inspector should be appointed who will periodically inspect the men's hands, and see that all superfluous grease is removed. Lessons should be given twice a day on the proper way to hold a hammer and chisel. To make absolutely sure, any man engaged in chipping should be enclosed in a boiler plate compartment. Men operating lathes shall be provided with a suit of mail and asbestos gloves in case of being burnt with flying chips. Men engaged in grinding operations shall be located in another room, and watch the operation through a periscope. We might go further, but have fear of being mistaken for a safety expert.

Safety first is an excellent motto, but should be attended with a little common sense.

Where Angels Fear To Tread

THE ubiquitous reporter may well be pardoned for his lack of technical knowledge, although the errors in the daily press often endow those better informed with homicidal tendencies. And while the average newspaper description is inaccurate and misleading occasionally, it is something more—a gem of the purest unconscious humor.

This is the case in connection with a description of a new steel mill which recently appeared in one of the daily newspapers of one of the Maritime provinces. It must be understood that the editors of POWER HOUSE are not responsible for the technical details nor the language in which they are clothed.

Here is how an ordinary conveyor is described:—

> "The pathway in the main resembles a tread mill, minus the angle of elevation—minus the horse, but not horse-power—with this difference, too, that the plate-mill conveyor is made up of rollers which have individual movement, and do not speed along in flattened spheroid assembly and connection as is the case with the tread mill as we know it when moving under the horses' feet."

After a description of various portions of the mill the article goes on to speak of the ingots:—

> "Meanwhile—and now that the way of the plate is made clear — what of the ingots?" (Almost biblical in its rhythm.)

With the making of steel we have little to do, and it is in the description of the power plant equipment that the stationary engineer is most interested and in which he will find most entertainment.

> "When one is told that the process just described calls for 4,000 horse-power from the electrical motor having a place along with a 65-ton flywheel in the adjacent alcove or annex, the reason for direct service by a main shaft of twenty inches leading straight from motor to rolls and mill machinery should be apparent. So, too, now are realized the purposes of the mighty, massive and deep-laid foundations of ferro-concrete underlying the same machinery and robbing it of vibration.
>
> "As illustrative of the electric power required in rolling a plate, a motor which serves this operation is the largest in Canada—so large, in fact, that its component parts defied transportation in anything like assembly. It arrived piece-meal, and over two months are necessary to erect it on the specially-prepared foundation designed to bear the 5,000 tons of dead weight thrown upon it and to neutralize the vibratory force that comes from the 32 revolutions per minute as a result of the 4,000 horse-power. The motor frame is 22½ ft. in diameter, studded with 170 units of lamination, each unit being made up of innumerable thin metallic strips held together and contained in insulated cases; all necessary in the development of the alternating current of 6,600 volts by 'mill type induction process.'
>
> "This is the species of electric power which kills people who come in contact with it, as opposed to the harmless incandescent sort when transformed for domestic use. The technicians could tell you much about this electrical machine built for 60 cycles and 3-phase with a momentary overload of 300 per cent., as well as its calculated economies in the use of current; the percentages saved by dynamic leaking and all that sort of thing. But when told the writer, he only scratched his head and looked wise. . ."

Progress in New Equipment

STEAM JET ASH CONVEYOR ENJOYS LOW MAINTENANCE COSTS

By Guy S. Hamilton

Some engineers, who are not quite convinced of the desirability of the Steam Jet Ash Conveyor, often point to maintenance as evidence of the uneconomical condition surrounding its use.

It is quite true that the abrasive action of the ashes as they travel through the conveyor pipe has a tendency to wear away the conveyor at the more vulnerable points.

This is a condition that cannot be avoided. A conveyor in constant use must wear. No pipe is made that is indestructible.

The American Steam Conveyor Corporation, after much experience in steam jet ash disposal have developed an especially chilled iron known as American Hard Metal. There is perhaps no harder metal on the market and yet, hard as it is, it must wear if enough ashes are discharged through the conveyor line.

Advocates of the steam jet ash convoyer who have used the system for several years and have had actual experience with its operation make usually strong assertions concerning the low maintenance charges of the conveyor. The true way, they say, to find the cost is to consider it from a standpoint of cost per ton of ash handled.

If the conveyor is in constant operation, if a score or more tons of ashes are discharged through it, the grinding and abrasions of the ashes on the pipe and fittings will, of course, be moderately large. If only a few tons of ashes are daily discharged, the abrasion will be proportionally less; if the system is standing practically idle, the wear will be little or nothing.

The use of the conveyor will determine to a large degree the maintenance charges for the system. An investigation into the maintenance costs of a number of large plants using American steam ash conveyors over a period of years bears out this assertion.

A well-known Wisconsin power company have three water tube boilers, each developing 500 h.p. Jones stokers, in use, and the resulting ash produced amounts to 500 tons during the year. In this plant an American steam ash conveyor is used to handle the ashes. The suction line is 65 feet long and the discharge line is 63 feet long. The ashes are discharged into an ash bin from which they are later withdrawn into a wagon.

This conveyor has been in service for three years and the total repair expense has been $66.20 which equals $0.0044 per ton of ash handled.

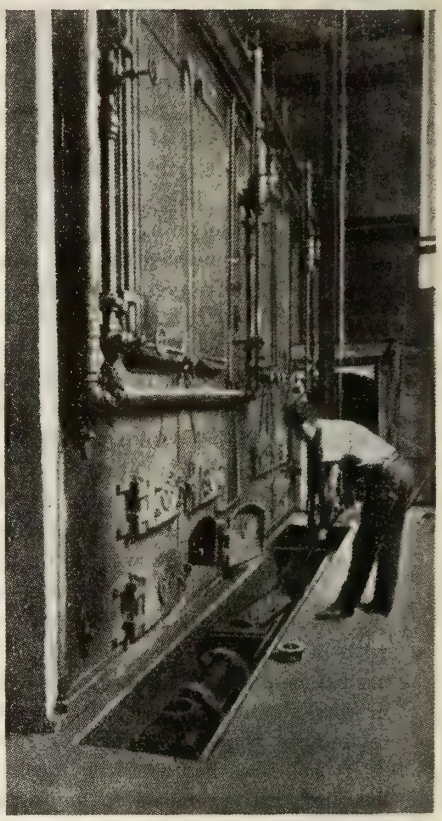
With total maintenance charges at less than one-half a cent a ton, it is doubtful whether any other type of conveyor could handle the ashes so economically and satisfactorily.

Another Wisconsin manufacturing concern has a power plant containing boilers totalling 7,050 h. p. A Jones and three-chain grate stokers are used in this plant. The suction line of the conveyor is 104 feet long and the riser is 62 feet high. The ashes are discharged into an ash bin from which they are later removed into cars.

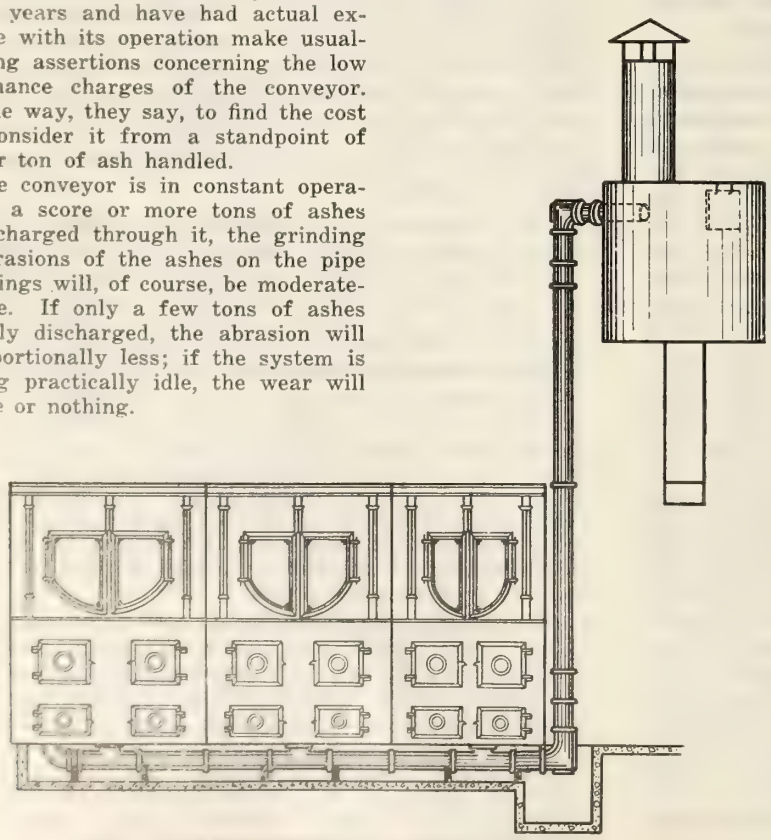
Each year 10,050 tons of ash are handled through this conveyor. The system has been in operation two years and two months, which means that a total of 24,550 tons of ashes have been handled. During this time the repair expense has amounted to $504.48, which figures out 2 cents a ton flat as the maintenance charge.

From these two instances, which have been duplicated many times, it will be seen that the maintenance charges of a conveyor handling an enormous quantity of ashes, is decidedly the reverse of excessive when the cost per ton of ash handled is considered.

This two cents a ton takes care of the depreciation and as the repairs are made, the conveyor is virtualy restored to its previous first-class condition.



SHOVELLING ASHES INTO THE CONVEYOR.



ARRANGEMENT OF CONVEYOR SYSTEM.

The Operators' Point of View

GRADED CERTIFICATE CORRESPONDENCE

The Editor:—Some interesting letters have been published in reference to the new license law for engineers.

One thing in connection with it is obvious to the real engineer, that is, its defects.

The public is not worrying whether an engineer can answer a lot of technical questions, analyze coal, build an electric generator, or figure water and fuel consumption to a fraction of a pound, and every law passed is supposed to be for the benefit of the public. Executive ability and technical knowledge are of interest to employers only in this law. The legitimate purpose of a license law should be to protect life and property and not to discriminate between or abrogate the rights and privileges of citizens.

Engineers having technical and special knowledge of financial value to employers could have a diploma, altogether separate from an engineer's license. There are hundreds of men capable of passing a technical examination and securing first-class papers, who would be "up a tree" if they were forced to take charge of a second-class plant and do the work themselves. I have seen "chiefs" who could pass a technical examination, figure efficiencies, talk like a "blue streak" about engineering, boiler construction, etc., and could not make as decent a job as many so-called third-class men.

As before remarked, the aim of an engineers' license law should be to protect life and property. Does our new license law do this? Not on your life. Most of the plants under 300 B.H.P. are located in cities and towns, under the roadways, sidewalks, and in the basements of buildings; in these plants second and third-class men will be in charge of the boilers. Over the boilers will be hundreds of people at work, unconscious of the fact that under them is located a force that, through ignorance or carelessness, may send them to eternity. And yet this force is entrusted to the care of a man who, the law says, is only part of what an engineer should be.

The first-class license leaves its holder free to earn his living in large or small plants, the second-class licensed man can only earn his living in the small plants, although altogether likely he is just as good and safe an engineer as the former. The natural result will be that the wages of the lower grade license holders will be reduced in time, for the employer is no fool, and will soon learn that his engineer cannot leave his employ unless he is prepared to take a position in a small plant. But if the first-class license man loses his position he can take a position in a small plant until he locates a better job. It may be remarked that the remedy is in the hands of the engineers themselves, all they have to do is to start in and study. It is easy to talk, but there are thousands of middle-aged men, and even many young men, who find it practically impossible to learn and hold a lot of technical knowledge. An honest, just license law is a mighty fine thing, but I am thinking the framers of our license law had a very limited knowledge of engineering conditions outside of their own small circle. I say small, for I feel sure that very few of the engineers who are used to thinking about the trials and troubles of the vast majority of safe engineers outside of their own immediate friends, had anything to do in securing legislation for this very unfair law. Surely if a man is safe with 300 B.H.P. he will be safe with 1,000. There would not have been so much dissatisfaction and there would not have been so much injustice done, if second-class licenseholders had been allowed to handle plants up to this size.

Can nothing be done to remedy this rank class legislation? The editor of this journal should be able to suggest some remedy.

JAMES E. ELLETHORN.

THE CONSERVATION OF COAL

The Editor of Power House:

Regarding the shortage of coal experienced again this winter for power boiler furnaces. The several provincial governments have by-laws for the inspection of steam boilers with inspectors for the protection of life and property, against boiler explosions, but such inspection does not include the condition of the furnace for burning the coal under the boiler.

Having had a life experience, I have seen many plants in factories in a condition not conducive to the conservation of coal.

It is quite possible for from 10 to 50 per cent. of the coal used in many such plants to be burned to waste, through faulty setting of the boiler and furnace or through infiltration of air which, of course, reduces the temperature of the product of combustion, necessitating more coal. Every pound of soft coal requires the oxygen contained in 12 pounds of air, more or less is harmful. Now it is just as impossible for a stoker to know when he is feeding the furnace with the right amount of air without a draft gauge and a flue gas recorder as it would be for him to know the pressure of steam on his boiler without a pressure gauge. Although these instruments have been on the market several years, their use is not yet universal. It is doubtful if we should experience such a coal shortage if their use was made as compulsory as a steam gauge on safety valve. Ships of the American navy can now steam 31 per cent. further on a ton of coal than previous to using them.

Scientific combustion of coal saved one manufacturing firm $200 per day. Another firm, $350 per week, a small factory after installing such instruments saved $1,000 per year in coal.

An electric light company saved $2,500 the first year of their use.

A test was made with six central heating plants in the States resulting in a saving of a quarter million dollars in coal.

Now, Sir, if all factory boiler furnaces throughout the country were inspected by experts and a license to burn coal issued only to these plants that were in a condition to burn it within a reasonable percentage of efficiency, it would result in much good to everyone.

The writer has seen boiler plants that were 87 per cent. efficient, also plants that did not show 40 per cent. efficiency.

The gauges have daily or weekly recording charts. Some there are that will record in the manager's office just what his battery of furnaces are doing.

I have not the least hesitation in stating that no man can hope for complete combustion of the coal without them. Even assuming that his brick work is air-tight (which is a rare case) or that his combustion chamber bridge wall or percentage of air space in grate is right.

No man wishes to burn coal to waste. Especially our factory owners in these days of high cost of everything and keen competition, yet strange to say many are doing so.

The day may dawn when every engineer of a factory will be asked to explain why his furnaces exceeded so many pounds of coal per square foot of grate surface per hour, more than was necessary for the heat generated or power developed. Faulty transmission is another cause of waste of coal, bare steam lines is another cause; radiation from some of cause means condensation of steam, that in turn means loss of pressure, away goes more coal, for the

engines must have the pressure or the machinery will stop.

The writer heard of one company that saved 33 carloads of coal in one year by insulating their steam drums and mains, Much progress has been made in locomotives since the days of "Puffing Billy," but there is yet room for the builders to do some serious thinking in order to reduce the coal consumption which is rarely above 50-65 per cent. on the thermal efficiency obtained in the boiler.

The suggestions offered for saving of coal in power boiler furnaces are not pet theories of mine. Every engineering college professor knows that what I herein state are facts, so would also the American Society of Mechanical Engineers, with which I have the honor of being affiliated.

Knowing these matters as I do, I would consider it a duty to my fellow man and country to make the same known to others for our very existence in this climate depends on coal to keep life in our bodies, besides we should use this gift from Him who made this world in such a manner that we will leave some for those who come after us.

Ottawa, Ont. J. S. KINGSTON.

THE TECHNICAL PRESS AND OTHER THINGS—MAINLY GRADED CERTIFICATE

Are you a reader of technical journals? If not, take the advice of an old fellow and start early.

If I could not secure my POWER HOUSE and other journals, I would feel isolated from the engineering fraternity, for in its pages the ideas, researches, and experiences of many engineers are given me.

The letters suggest topics for discussion, and often give valuable tips, such as can not be found in any text-books.

The question and answer page is the journal reader's consulting engineer. Often the answer given some engineer to a question is just the information he was wanting.

Your employer is apt to form a better opinion of your ability than he formerly held when he notes the regular delivery of your technical journals in the factory mail. The selling section is not the least interesting or the least valuable; only a day or two ago I applied to a local dealer in electrical goods for an article which had been advertised in an engineering journal for some weeks past; he had not even heard about it. I showed him the advertisement, and he is going to put in a supply.

Graded Certificates

Engineering pays, and many good men are making a living in the ranks. It is too bad that politics is allowed to disrupt these same ranks. This is in respect to the graded certificate. Some few years ago the leading stationary engineering journal in the United States said in an editorial that the grading of engineers' licenses seems a little out of place in this day.

The object of the law is wondered at by those who have not been instrumental in procuring its enactment. Of course, the ostensible object is to provide safe men for the operation of steam machinery. The real object seems to be, on the one hand, an attempt to limit the supply of engineers. On the other hand it looks like a scheme by which the engineer is made to pull the chestnuts out of politics for a set of inspectors, who can make or break engineers (?) on any old occasion.

A physician is examined by a committee of some sort and allowed to practise medicine. The kinds of disease which he may legally treat, or the size of a leg he may saw off, are not specified. In other words, the patient dies, anyway.

A pharmacist is registered. It is not stated in the permission given him to distribute drugs that he must only compound prescriptions containing vegetable poisons, while arsenic and calomel must be mixed by a man with a special license.

It would seem that an engineer is, and must be, as much of an engineer if he knows and is safe about a 300 B.h.p. plant and a 5-ton flywheel, as if he were competent to take charge of a 5,000 B.h.p. plant, or 20-ton flywheels.

The dear public has a right to insist that those mysterious forces, expansion of steam and the centrifugal force of the revolving flywheels should be handled only by a safe, sane and conservative man. Engineers should get together, in the lodge room and elsewhere, and form plans to get this Bolshevist-making law changed. Get after Mr. Drury, get after your member, get after your editor, the last named can do a lot if he will only do it.

The second-class license should allow its holder to take charge of any sized plant. Common sense will only be needed to understand that, so far as safety is concerned, he will be just as good, and, perhaps, better, than the technical first. It is all right to have the technical first-class license, give it to any who desires it, and it will be up to the employer to take the so-called high-class man if he wants him. But, brother engineers, it is up to you to put up a strong fight to have this unfair law changed; start at once and do not quit until justice is secured. This license law is unlike the usual Canadian laws. It will give a few men a soft, easy living and prove a hardship and a heart-break to many.

It is the worst piece of injustice ever put through here to hold back an army of honest, hard-working mechanics. I believe that this is not alone my personal opinion; every engineer, without exception, to whom I have talked this matter over, is of the same opinion. Forcing the 2nd and 3rd class men to stick to small plants is the one big injustice. Why, in the name of sense, should a man be compelled to remain in a small plant because he is deficient in ice-making, or cold storage knowledge?

Oh, what is the use? The law is a punk one. The thing to do is to get it killed, or altered, the latter for preference.

JAMES SCOTCH.

TO THE STATIONARY ENGINEER

A number of engineering correspondents have written us respecting various phases of the Graded Certificate Act now in force in Ontario. Many of these letters have been more or less severe in their criticism of the Act, and while the pointing out of defects, real or fancied, is important and of value towards their betterment, little has been given in the way of constructive criticism.

No one is better able than the engineer himself to give suggestions as to improvements to be effected either in the Act or in the Regulations under which it will be carried out, and since each engineer has, or should have by this time, his copy of the Act and its Regulations, he should be in a good position to form his own opinions. Not only so, every engineer has no doubt given the matter considerable thought, and, having read both the Act and Regulations carefully, has his own ideas as to both, and can suggest improvements.

We are, then, asking that the stationary engineer send us a letter in which improvements and suggestions are embodied. No matter what your opinions are, send them in for publication and discussion. The requirements for examination, the type of questions which you think should be asked, the length of service, the size of plants for each certificate, and similar matters are all suitable subjects for discussion.

It is only by free discussion that any legitimate change can ever be brought about, and the columns of POWER HOUSE offer an ideal medium for the freest discussion, leading eventually to a crystallization of the general thought of the engineers of the Province.

One thing more, and equally important—the education of the engineer should be an important feature of the educational system of Ontario. The Department of Education has taken a long step forward by establishing night classes for the engineer throughout the Province. Since these have only been functioning since the late fall, in most cases, it is possible that the subjects taught might not be just what you require, or the courses in other ways could be bettered. Let us have your thoughts regarding this, and send in your suggestions as to what you would like to see taught, and how.

Coal Dust as an Explosion Hazard

Partially Consumed Coal Dust Has Been Found by the U.S. Bureau of Mines to be an Explosion Hazard in Steel Mills Where It Readily Collects on Structural Work

By L. D. TRACY

FOR many years natural gas has been the principal fuel used in the heating furnaces in those mills located in the Pittsburgh district which manufacture bolts, nuts, rivets, picks, mattocks and small forgings.

For a number of years the steady supply of this fuel has been more or less interrupted owing to the increased demand for domestic use and to the increasing difficulty in securing an adequate amount of natural gas.

This condition has led a number of the steel companies to substitute pulverized coal as a fuel for the furnaces. Elaborate installations have been made for pulverizing the coal and conveying it to the furnaces. Soon after the furnaces commenced to operate with pulverized coal, large quantities of fine dust began to accumulate on the platforms over the furnaces, the roof trusses, on the outside of the various pipe lines, electric cables and even on the roofs of the buildings.

Some of the companies, becoming alarmed, requested the Bureau of Mines to make an investigation to ascertain the liability of this dust to cause an explosion.

While conducting this investigation, an explosion occurred in another mill which caused the death of one man and severely burned two others.

Eleven samples of the dust (which for convenience has been termed "mill dust") from various locations in the different mill buildings were taken and submitted to chemical analyses, microscopic examination and also to flame and explosion tests.

From the chemical analyses it was found that the volatile matter in the dusts ranged from 6.3 per cent. to 23.54 per cent., fixed carbon from 50.88 per cent. to 67.08 per cent. and ash from 22.29 per cent. to 32.16 per cent.

Five samples of the pure coal dust, before passing into the furnaces, were subjected to a chemical analysis and it was found that the volatile matter in the coal ranged from 30.50 per cent. to 36.81 per cent., the fixed carbon from 46.86 per cent. to 52.48 per cent. and the ash from 9.26 per cent. to 21.84 per cent.

Under the microscope a sample of mill dust, which by chemical analysis showed 23.5 per cent. volatile matter, was found to contain a very large proportion of very fine partially coked coal dust, a small proportion of fine or medium fine partially coked coal dust and some dust thoroughly coked. In addition, a considerable portion of yellow resinous appearing matter, some particles of carbon which might be termed soot and some small particles of ash were found.

A sample, which by chemical analysis was found to contain but 11.25 per cent. of volatile matter, under the microscope showed only a relatively small proportion of medium sized partially coked coal dust and many thoroughly coked particles.

From these examinations and analyses it would seem seem that, for some reason, the puverized coal was being blown out of the combustion chambers of the furnaces before it had been thoroughly consumed.

The several samples of dust were also subjected to tests to determine the pressure which might be exerted by the dust in a possible explosion as compared with pure pulverized coal; this test was conducted in the Clement-Fraser apparatus (described in Technical Paper 141 of the Bureau of Mines). Briefly, this apparatus consists of a glass globe, possibly six inches in diameter, containing a small platinum coil which is electrically heated. A sample of dust is blown against the heated coil and the pressure of the resulting explosion is recorded by a pressure indicator. In these tests about 0.003 of an ounce of pure pulverized coal was blown by about eight cubic inches of oxygen under a pressure of five and one-half inches of mercury against the platinum coil which has been heated to a temperature of 2200° Fahrenheit. The average pressure obtained was 14.5 pounds per square inch.

A sample of the dust, containing 23.54 per cent. volatile matter, exploded in the apparatus with a recorded pressure of 10.21 pounds per square inch, a second sample containing 20.6 per cent. volatile matter recorded a pressure of 8.7 pounds per square inch and a third sample with 15.91 per cent. volatile matter recorded a pressure of 4.6 pounds per square inch.

It will be noted that the sample containing 23.54 per cent. of volatile matter registered a pressure but little under that of pure coal dust.

When the small quantity of dust which was exploded is taken into consideration and a pressure of over ten pounds per square inch is obtained, it will be readily seen that, with a large amount of dust exploding, the pressure would run much higher, if confined.

Further experiments to determine the explosibility of the mill dust were carried on in the dust explosion gallery of the Bureau. This is essentially a horizontal wooden box, six inches deep by six inches wide and fourteen feet long, made of 2-inch planks, held together by wooden clamps and iron rods, in such a manner that the top may be removed. A metal flap valve covers the back end of the gallery, the other end being left open. At uniform distances along the entire length of the floor of the gallery are 14 holes, into which are fitted ¾-inch pipe jets projecting vertically from a 2-inch horizontal pipe extending beneath the floor of the gallery. The back end of this pipe is closed by a cannon having a capacity of about one-fifth of an ounce of powder, the other end being left open. A loose metal disk covers the end of each jet leading into each hole in the floor of the gallery, thus forming a pocket for the dust, about one-tenth of an ounce, with which each hole was loaded.

Each hole is covered by a small square of coarse, heavy screen held in place by large washers bolted to the floor of the gallery. The purpose of this screen is to diffuse the dust into a cloud of more uniform density.

The gallery was loaded by pouring about one-eighth of an ounce of the "mill dust" in each of the fourteen holes in the floor of the gallery. The squares of screen were then placed in position over each hole.

The cannon in the end of the horizontal pipe beneath the gallery was loaded with about one-sixth of an ounce of powder, and about a third of an ounce of loose powder was placed between the first two holes in the floor of the gallery. After the loading of the gallery had been completed, the top was bolted on and the electric firing wires connected. The explosion of the powder in the cannon served to raise a dust cloud and the loose powder was used to start the initial explosion of the dust cloud.

The cannon and loose powder were fired by means of electric spitters, the cannon being fired two seconds before the loose powder.

From experiements made in the Fraser apparatus, it was believed that the division point between explosibility and non-explosibility would be found in dust containing between 10 and 15 per cent. volatile matter.

Two samples, one containing 13.45 per cent. and one containing 10.99 per cent. volatile matter were tested in the gallery. The first sample was found to be quite explosive, while the one containing 10.99 per cent. is less explosive and would probably require an initial explosion to ignite it.

Tests were also made to determine the inflammability of the dust, one of these being the heating of a clay roasting dish, six inches in diameter, in a furnace to a temperature of 2,000° Fahrenheit. When the dish had reached this temperature, about one-sixth of an ounce of "mill dust" was quickly dropped in a cloud upon it.

Another test was made by blowing a small amount of the dust in a cloud across the flame of a Meker burner.

These methods of testing were valuable as they were almost identical with

the conditions in and around a steel mill where the red hot iron and steel are often in close proximity to clouds of dust.

Two samples containing 20.60 per cent. and 23.54 per cent. of volatile matter burned readily and with more or less explosive violence.

Three samples containing 11.5 per cent., 13.45 per cent. and 15.91 per cent. of volatile matter burned readily, but without the violence of the two preceding samples.

Two samples containing 11.25 per cent. and 10.99 per cent. of volatile matter were found to be slightly inflammable and one with only 7.17 per cent. of volatile matter would not burn at all.

From the above described tests and from similar tests with dust from the steel mills of other companies, it has been fairly well demonstrated that the division point between mill dust which will explode and that which will not explode, is reached when the dust contains about eleven per cent. of volatile matter.

A good example of the great danger from mill dust, caused by the use of pulverized coal, is the fire which occurred a few years ago in a plant in which there were a number of puddling furnaces, some of which used pulverized coal as a fuel. A draft of air blew some of the coal dust over some red hot iron or slag. The dust immediately ignited and communicated the flames to the roof trusses. These were covered with fine dust which caused the roof to burn so quickly that the men barely escaped in safety from the building.

Many of the systems distributing coal dust to the furnaces consist fundamentally of fans which drive the dust from the storage bins through large pipes, from which small feed lines lead to the burners. It is the practice in some mills, when the furnaces are shut down, to stop the fan before all the pulverized coal in the pipe line has been thoroughly blown out. This is a rather dangerous practice for the reason that, when the pressure from the fan is stopped, there is liable to be a back draft from the furnace which may take live sparks into the feed line. These sparks will smoulder until the fan is started again and then will be fanned into a flame, igniting the dust in the feed line with a consequent explosion. The fatal explosion mentioned in the first part of this article was evidently caused in this manner.

The roof trusses, pipes, platforms and all other places upon which any considerable amount of dust might accumulate should be kept thoroughly cleaned. In cleaning these trusses, platforms, and so on, no flame torches or open lights should be used because of the danger of igniting any dust cloud which might be raised.

All electric switches and motors should be kept from dust and all electric wiring should be kept away from any place where dust in large quantities is liable to accumulate. As far as possible the wiring should be carried in conduits.

Provision should be made to protect properly all pulverizing machinery from damage which might be caused by an explosion due to the ignition of coal dust from static electricity in the machinery. All conduits, grinders and other parts in which an electric spark is liable to be produced should be grounded. Care should be taken that there is no way in which the coal dust can come in contact with hot metal; especially where pulverized coal storage bins are in close proximity to hot metal or hot slag.

In some of the furnaces in which natural gas has been used, it is customary to keep both the gas and pulverized coal connections ready for service. If coal is being used, the gas connection should be cut out as there is a chance that a leaky valve may allow gas to accumulate in the main coal feed and become ignited by a back fire from the furnace.

The substitution of powdered coal for natural gas in the heating furnaces of the steel mills is of comparatively recent date, and there is hardly any doubt but that the practice will become more general in its application as an adequate supply of natural gas becomes more difficult to obtain.

As the problem of mill dust and the consequent danger therefrom seems to be prevalent in some plants using pulverized coal, it would seem imperative that every mill official should take precautions to prevent loss of life and property by an explosion or fire from this dust. —U. S. Bureau of Mines, Reports of Investigations.

NOTES ON LIGNITE

Continued from page 65

"Efforts are being made in France to introduce the distillation of lignite for tars. The Societe de Distillation des Combustibles, Paris, is constructing an improved Zeigler type of furnace similar to that used for the distillation of peat, a type yielding about 7 per cent. of tar.

"In one place in Germany, where the system was adopted, 70 to 80 per cent. of marketable products was obtained from lignite tar, namely 15 to 20 per cent. paraffine wax, 5 to 20 per cent. kerosene; 5 to 15 per cent. of creosotes and organic acids; the remainder being light products, petrol, etc., or heavy products such as gas-oils, and lubricating oils.

"Concurrently with the great interest taken in the development of the shale-oil industry in America, it is worth while to consider the possibility of utilizing the large deposits of low-grade lignites for another set of greatly-needed chemicals, including the fixed nitrogen, which can be converted into ammonium sulphate. Among the available products are benzol and toluol, and the gas can be employed in many places for industrial purposes." (Mining and Scientific Press, May 11, 1918.)

If we are to prevail against our enemies in time of war and maintain our commercial prestige during peace, we must not be less diligent than either friends or foes in the matter of developing and conserving our natural resources.

In respect to the world's future demand for fuel oils, the "London Financier," the leading financial paper of London, says in a recent issue:

"Of all the commercial propositions of the world, probably none has greater potentialities than the oil industry. Although throughout the centuries a staple product of the earth, oil, until comparatively recent years, was never utilized to any extent as a motive power owing to the poverty of invention in respect to engines adequate for its proper exploitation in that respect.

"The war, however, has brought about many wonderful changes, necessity having truly proved the mother of invention, and, among other things, oil engine invention has received a vast stimulus, with the result that perfection in the manufacture of the necessary machinery is now being rapidly approached, and, at the same time, scope for the usefulness of liquid fuel enormously extended.

"It is indeed quite reasonable to prophesy that the next generation will witness the practical disappearance of coal as the motive power for railways and ships, so that 'King Oil' may become a greater potentate on both land and sea than the veteran monarch of motion, 'King Coal.' "

A market for the fuel oils derived from carbonization of lignite is assured.

This project of developing our lignite resources is not a small matter.

Take the North Dakota section as an illustration:

Into this section there are now being imported a minimum anual tonnage of two million tons of bituminous coal and one million tons of anthracite, every pound of which should, and some day will, be replaced with fuel from the Dakota lignite field.

To replace these three million tons would require the carbonizing annually of six million tons of lignite, yielding three million tons of solid fuel, 18 billion cubic feet of surplus gas (costing nothing), 45 thousand tons of sulphate of ammonia, and 60 million gallons of tar distillates, comprising benzol, carbolic, creosoting and anthracene oils, paraffin, etc.

The waste in dollars and cents involved in two years' importations of the foreign coal into that territory would probably pay for all the equipment necessary to carry on the industry on the scale outlined.

Bear in mind, too, that the Texas lignite situation affords an even greater opportunity for economic saving. The opportunity in Alaska must be nearly, if not quite as large. And there are many smaller deposits of lignite scattered over the southern and Western states where relatively smaller savings can be made in similar fashion.

In several sections of Texas there are merchantable deposits of iron ore. Limestone is close at hand. The development of these deposits has been unprofitable because of the high price of coke, but under the present stimulus of high prices for pig iron, a blast furnace will soon be put into operation at Rusk, notwithstanding the fact that the Alabama coke,

NOTES ON LIGNITE

Continued from page 72

which will be used, will cost $16 per ton at Rusk. The carbonized lignite, or the carbonized lignite briquets, should replace coke at not more than half the price. The lignite, iron and limestone lie within a few miles of each other. The development of a steel industry in Texas surely should obviate the necessity of large shipments of iron products from eastern United States into that section.

The concerns now engaged in mining lignite are not strong financially. They cannot afford to hire the technical and engineering skill which can be supplied by the Bureau of Mines. They need and are asking for help, and it is believed that a measure of governmental assistance on the technical features presented is amply warranted.

While any encroachment by the Government upon what is popularly deemed the field of private industry may be looked at askance by the public; yet, if the nation's natural resources are to be conserved and the fullest possible benefit gotten from them, some authority having a wider vision than any single industrial concern intent upon earning dividends must exercise a certain degree of surveillance and afford a measure of constructive help in co-ordinating the innumerable features of industrial interrelationships. A constructive economic policy of this character is a true Government function and should insure rather than jeopardize legitimate gain from private enterprise.

Our pride should be not in our mere possession of this bountiful land,, but in the extent to which we discover its resources and in the degree of efficiency to which we devote them to the service of mankind.

CANADIAN RAILWAY CLUB HOLD MERRY TIME AT ANNUAL DINNER

THE seventeenth annual dinner of the Canadian Railway Club was held on the last night of January, at the Windsor Hotel, Montreal. About 300 were present at the tables and all did justice to the food (and drink) placed before them. The dinner was presided over by J. Hendry, president of the club, with Lewis C. Ord as toastmaster. The Hon. Arthur Meighen and Rev. George Adam were the guests, and with them at the head table were: W. M. Neal, late secretary of the Canadian Railway Board; W. H. Winterrowd, H. H. Vaughan, J. M. S. Carroll, R. M. Hannaford, Jas. Coleman, W. H. Sample, T. C. Hudson, W. McNab, A. A. Goodchild, W. A. Booth, A. A. Maver, Wm. H. Robb, W. A. Kingsland, Norman Holland, and G. M. Wilson.

In proposing the toast to "Our Railways," W. H. Winterrowd gave a brief resume on the history of railroad development in Canada from the time that the first train was put in operation 92 years ago, up to the present time, particularly emphasizing the effective special service rendered by the railroads during the past five years. The reply to this toast was ably given by W. M. Neal, formerly general secretary of the Canadian Railway War Board, and recently appointed as assistant general superintendent of the Quebec district of Canadian Pacific. His brief address was largely taken up by a review of the achievements of the Board in getting the effective co-operation of the various railroads under the auspices of the C.R.W.B., whereby there had been great saving in labor and operating costs. Mr. Neal gave numerous figures to illustrate his remarks.

The toast to "Our Guests," which was proposed by T. C. Hudson, was responded to by the two chief speakers of the evening, the Hon. Arthur Meighen, Minister of the Interior, and Rev. George Adam. In his address, Hon. Arthur Meighen spoke on the gradual, but progressive, development of Canadian railroads, and defended the policy of the Government in their acquisition and control of additional mileage. He emphasized the changing industrial conditions that were virtually forcing the Government to take over the Grand Trunk. In speaking on this matter he said: "I pass the subject up only with the statement that that acquisition, like the previous one, was not brought about through any restless ambition to become great railway operators and owners, but it was the result of our railway crisis, the result of some mistakes and, indeed, of the very evolution of railroads.

The first instalment of machinery and power equipment that will be used in connection with the new plant of the St. John Dry Dock and Shipbuilding Company, at Courtenay Bay, has been delivered to the site. This shipment consists of four carloads and will form part of the twenty carloads that will be required to fit out the plant. The machinery, when unloaded, will be stored in an adjoining warehouse until the buildings are ready to receive it.

W. & G. FOYLE, Ltd.

12-125 Charing Cross Road, London, England

WANTED

Representatives to handle special line of British made "Elastic Steam Jointing Cement" (for all joints) and Iron Cement for casting, etc. Exclusive territory offered parties conversant with trade. Replies treated confidential. Apply Box 151, Power House.

OPPORTUNITIES

TENDERS INVITED

SEALED tenders will be received up to and including March 1st, 1920, to cover the installation of a distribution system of electric lighting in the town of Capreol, Ontario. Plan and specifications on request.

W. H. MATHEWS,
Town Clerk.

WANTED

First-class machinery draftsman, by large Canadian in city near Toronto. In making application give details of experience, age and salary desired, etc. Apply Box 205, Power House.

WANTED

Power House Engineer, holding second-class Provincial certificate as assistant to chief engineer, for large industrial plant near Montreal, must be experienced in the operation of D.C. generating sets, transformers, air compressors and hydraulic pumps. Permanent position for the right man. Applicants speaking English and French given preference. State experience, qualifications, age and salary expected. Box 206, Power House.

Where Do You Live?

We are going to put a representative in every town in Canada. Be the one in your territory.

We teach you how to build a permanent, substantial business. Whole or spare time. Write for particulars to-day.

Dept. B., Agency Division
153 University Ave., Toronto, Ont.

STATIONARY ENGINEERS — THOSE WHO wish some practical tuition for their Graded Certificates from a practical power house engineer holding highest certificates are invited to communicate with T.H.F., Box 208, Power House.

Manager wanted, for Canadian National Newspapers & Periodicals Association. To act also as Secretary-Treasurer, and carry on the Association's general work, under the direction of the President and the Board of Directors, study the interests of the various classes of publications in the Association, and plan and carry on promotion work in their interests. Applicants should understand advertising and merchandising. Apply in writing only, stating age, full details of experience, and salary expected. Applications will be treated as confidential. Address Acton Burrows, President, Canadian National Newspapers & Periodicals Association, 70 Bond Street, Toronto.

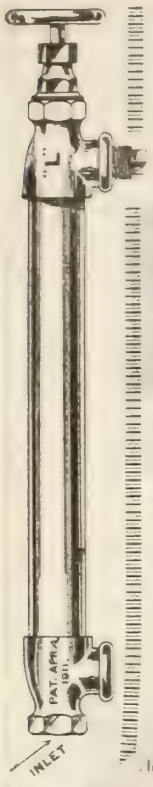
Use The LONG STEAM for TRAP SATISFACTION



Automatically drains jacket kettles, separators, steam mains. Works against 1 to 200 pounds pressure. Has two outlets and is installed in any position. DOESN'T FREEZE.

The Hamilton Powder Works, Beloeil, P.Q., use them with great success. Read this letter.

Dear Sir: We have used one of your steam traps for a long time and have found the same to answer the purpose as well as any seen in operation. We were so pleased with the working of this steam trap last winter that we ordered six more this season and have fitted them up at various points in the works where live steam is used for heating purposes.

(Signed) J. Murray Wilson, Superintendent

Our trap will give you the same satisfaction as recorded above. Investigate and you'll be satisfied, too.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 24 TO 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

At the luncheon given by the Engineering Institute of Canada on the first day of the convention, a discussion on the growing necessity of new methods in the construction and maintenance of highways was a feature of the session. It was suggested that some federal system of co-ordination be adopted to build roads on regular plans throughout their length so as to adequately meet the requirements of modern motor traffic. The rapid extension of motor traffic made it imperative that a standard road should be maintained on the main highways, and that everything should be done to encourage some co-operative plan of permanent and uniform roadways.

Continuing to recognize the undersupply of bituminous coal for the full operation of nominal railroad service, officials of the Canadian roads have stated that with few exceptions the curtailment of trains and other activities, requiring coal as fuel, will be effective for some time yet. The duration of this period will depend on the severity of the winter and the time required to return the coal supply to normal.

Changes at Hamilton.—The Canadian Fairbanks-Morse Co. announce that Mr. R. V. Donaldson has been transferred from London to take charge of their business at the Hamilton branch. Mr. Dave White, who has been with the Canadian Fairbanks-Morse for some time in Hamilton, has started in business for himself in that city.

Five workmen of the Hall Engineering Company, of Montreal, were slightly injured while repairing a boiler at the Low Level pumping station, when a tube on an adjoining boiler burst, enclouding them in steam. Little damage was done to the plant, but the burns of the men were painful, but not of a serious character.

Pratt and Cady Co., Inc., have issued a folder entitled: "Take the Hobbles Off Production." This folder invites the reader to join in a movement for the reduction of the high cost of production by standardizing manufactures and by the use of standard lines wherever possible.

The Green Fuel Economizer Co. announce the opening of their own office at No. 1006 Finance Bldg., Philadelphia, Pa. The office will be in charge of Mr. W. F. Wurster, assisted by Mr. G. E. Kille. The company was formerly represented in this territory by the Baker-Dunbar-Allen Company. Mr. Wurster has been doing engineering and sales department work with the Green Fuel Economizer Company for the past six years.

Guelph After Six. — The Industrial Committee of the Guelph Chamber of Commerce met and dealt with the application of six American firms who are anxious to locate their Canadian branches in Guelph. The landing of two or three of the firms for the city looks very promising. A sub-committee was appointed to deal with the formation of a Guelph Realty Company. Committees to look up detailed information on the following subjects are to be appointed: Power factor sites, taxation, water, transportation and education.

New Light System. — Superintendent Williams, of the Canadian Pacific Railway, anounced that an automatic electric light system of signals is to be installed this summer on the 65 miles of Canadian Pacific railroad track between London and Toronto. The new system will save oil and labor. Mr. Williams also stated that practically a quarter million dollars will be spent by the C. P. R. on improvements in the division during the summer of 1920.

Are You Able to Turn Your Spare Hours Into Dollars?

If not—and you are really trying to cash in on the spare moments you have during the day or after working hours—if you have made up your mind to take hold of some proposition and sail right in and actually increase your monthly income without hindering your regular work—surely you will want to know about MACLEAN'S plan for making each spare moment count. And even if you are already making money during your spare time—still you can add to your income with very little additional efforts. For you can have full particulars of MACLEAN'S plan absolutely free. If you will merely drop us a card we will send you the complete details of this plan. It will cost you nothing to find out exactly how others with spare time have materially increased their monthly earnings. For full information or the agency in your locality, write and right now,

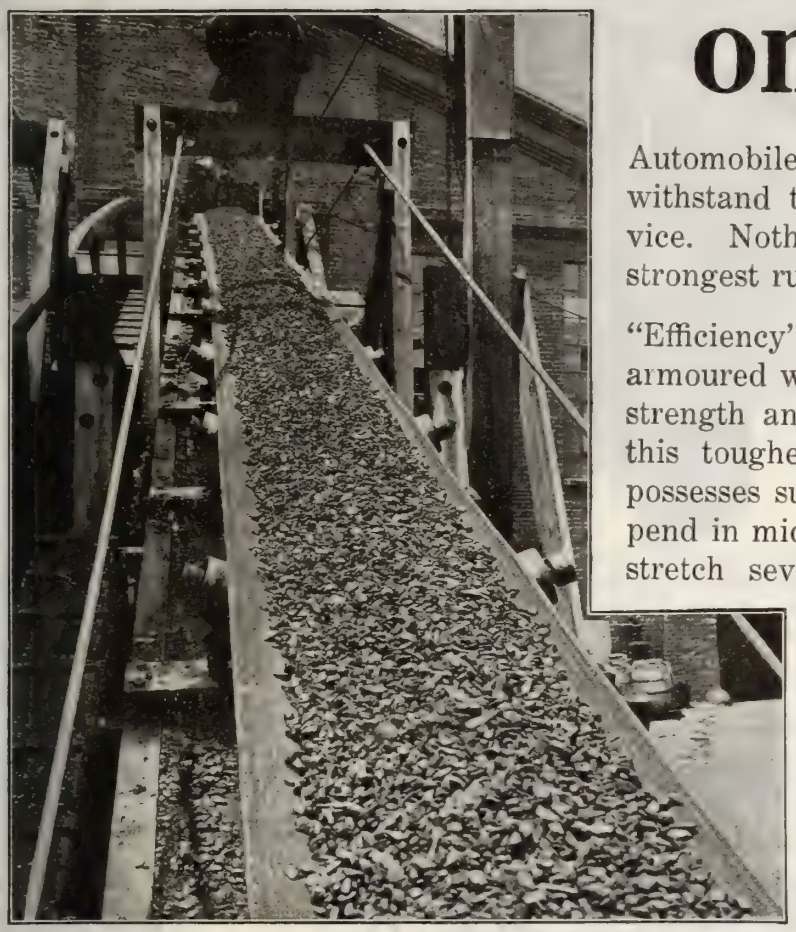
Conveyor Belts that Stay on the Job



Automobile Tire Treads encounter and must withstand the most abusive, abrasive service. Nothing but the very toughest and strongest rubber stock will stand it long.

"Efficiency" Conveyor Belts are heavily armoured with Tire Tread Rubber of great strength and elasticity. A single cord of this toughened rubber, one inch square, possesses sufficient strength to readily suspend in mid air a big load of hay and will stretch several times its original length without breaking.

"Efficiency" Conveyors, like highest grade Auto Tires, are made for the most exacting service.

Though of immense strength they trough perfectly, and, of their own weight, automatically conform to the idlers.

Other very important features in their construction we are unable to detail here, but they represent economy in operating cost for you. When in need of Conveyor Belting let us send a representative to demonstrate them.

Rubber Belting for Every Purpose.

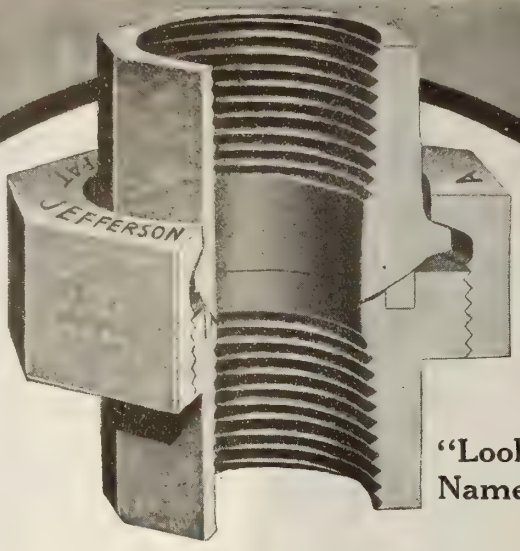
JEFFERSON



"Look for the Name on the Nut"

JEFFERSON UNIONS are particularly adapted to the requirements of underground pump service. The Brass Seat Ring makes a tight brass-to-iron joint which cannot corrode, and is easily disconnected. The Spherical Ground Joint takes care of alignment difficulties and makes possible a tight joint even if the line is not exactly straight.

And there are other important reasons why JEFFERSONS are better. "The Name on the Nut" protects you against substitute "just-as-good" unions. You would have a mighty hard time trying to make tight a leaky union with a "just-as-good" promise.

Ask your Jobber and JEFFERSONS. He knows every union that's made and can tell you just why JEFFERSONS are better. Write TODAY for our Catalog "UNIONS"

WILLIAMS' SUPERIOR DROP-FORGED CLAMPS

THERE'S a Williams' Clamp for every purpose.

If it's extreme strength and heavy service—Williams' "Vulcan" line provides both.

11 sizes, ¾ to 12½ inches capacities.

If it's general utility—without need for maximum strength—Williams' "Light Service" line will fit the case, 8 sizes, 2 to 12 inches capacities.

If it's stability and utility—medium service—Williams' "Agrippa" line offers the solution. 7 sizes, 4 to 18 inches capacities.

If it's Tool Room work requiring comparatively small openings of jaws — Williams' "Vulcan" Tool Makers' line should be chosen. 4 sizes, 1 to 4 inches capacities.

All are made of a special, high-grade steel. After forging they are submitted to a refining process, or "heat treatment," which increases their stiffness and strength and reduces the liability of springing.

Engineers' Tools Booklet on Request.

DEPENDABILITY!

THE Emergency Fleet Corporation accepts Sturtevant Electric Generating Sets because they are absolutely dependable in service.

Sturtevant
(TRADE MARK)

ELECTRIC GENERATING SETS

are built to U. S. Navy Specifications and accepted without alteration in design. They are carefully designed and built to give lasting satisfaction after long periods of severe operation. They are compact, self-contained units, consisting of a Sturtevant steam engine direct-connected to a conservatively rated Sturtevant electric generator. They are made with automatic lubricating systems, either gravity or forced feed. All reciprocating parts of the engine are entirely inclosed within the engine frame, which is provided with oil- and dust-proof covers. Removal of these covers gives ready access to all parts. Our Bulletin 239-U gives detailed facts about these sets.

UND. LAB. INSPECTED

ECONOMY Renewable FUSES Mean DOUBLE PROTECTION

ECONOMY renewable FUSES were approved—IN ALL CAPACITIES—by the Underwriters' Laboratories on Dec. 9, 1919—the old "APPROVED IN ALL CAPACITIES" renewable fuse using an inexpensive bare link to restore a blown fuse to its original efficiency.

Economy renewable Fuses—from 0 to 600 Amperes in both 250 and 600 Volts bear the Underwriters' approval label. Economy "Drop Out" renewable links also bear the inspection symbol.

There were millions of Economy Fuses in use before this approval was granted—a fact applicable to no other electrical device listed in the code as requiring approval.

Both the unrestricted use of Economy Fuses and the granting of approval were due to the fact that these fuses live up to all claims made for them — accurate, efficient, economical and safe.

The use of ECONOMY renewable FUSES means double protection—the dependability of the fuse itself—the regular inspection by the Underwriters' Laboratories.

Approved In All Capacities

Economy Fuses, approved in all capacities, ferrule and knife blade types, are stocked and sold by all leading electrical dealers and jobbers in the United States and Canada.

DEPARTMENT OF LABOUR

Ontario Government

Minister:
Hon. W. R. Rollo.

Deputy Minister:
W. A. Riddell, Ph.D.

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a STATIONARY steam plant of 50 B.H.P. or over, in the Province of Ontario, must hold a Stationary Engineer's certificate from the Board of Stationary & Hoisting Engineers. Anyone operating such a plant without a certificate is liable to the penalties set forth in the Act respecting Stationary and Hoisting Engineers.

After January 1st, 1920, the Certificate issued by the Board will be of four grades, viz., First, Second, Third, and Fourth. Application forms for graded certificates will be mailed upon request after the above-mentioned date. The certificates now issued by the Board will be graded into Third and Second-Class upon renewal, same being classified from the information contained in the renewal application which will be sent to each certificate holder.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse-power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a certificate is liable to the penalties set forth in the Act respecting Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1st, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request. The B.H.P. and other information contained in these forms is to be used for statistical purposes. A Registration Certificate will be issued to each applicant. All applications, or requests for same, should be mailed to the Chairman.

W. C. MCGHIE, CHAIRMAN OF BOARD

NOTICE TO MANUFACTURE DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, entering the Province of O tario, and boilers exchanged repaired, are subject to G ernment Inspection as prescr ed in the Steam Boilers' A 3 George V., c. 61.

Before any work of repair alteration is commenced on boiler, notice must be sent the Department stating the ture and extent of the repa or alterations proposed to made. If the Chief Inspec should consider such repairs alterations of an extensive ch acter, the boiler must be spected in accordance with Regulations by an Inspector thorized under the Act.

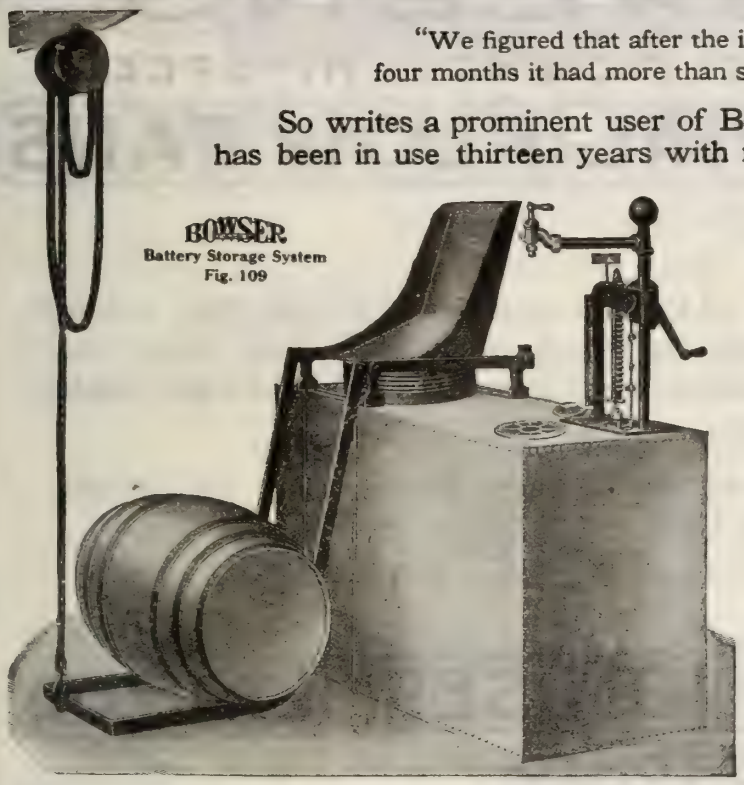
All communications should addressed to the Steam Bo Branch, Department of Labo Parliament Buildings, Toron

D. M. MEDCALF, CHI INSPECTOR OF STEA BOILERS

Why Don't You Save Too!

"We figured that after the installation had been in three or four months it had more than saved its entire cost."

So writes a prominent user of Bowser Oil Storage. Their equipment has been in use thirteen years with no operating troubles or upkeep cost.



If you are not using Bowser Storage Systems for your oils you are losing money every day.

What a Canadian Advertiser Says:

The following letter, by no means an exceptional one, accompanied a renewal advertising order received on January 10th, 1920. Such expressions emphasize the fact that our policy of "Efficiency in Power Plant Equipment and Service" is accomplishing splendid results for readers and advertisers.

"Gentlemen:—

"Enclosed please find our contract for space in 'Power House' for the coming year.

"I wish at this time to express my very high opinion of the value of your paper, both from an editorial and advertising standpoint. As a matter of fact, after many years' experience in space-buying, I have reached the conclusion that the value of space in a paper is of value to the advertiser in direct proportion to the value of the editorial matter to the reader. You certainly have a very capable editorial force, and we want to compliment you upon this feature of your paper as well as to express our thorough appreciation and satisfaction with the results secured through our advertisements."

Are You a Reader of "Power House"?

The subscription price is $2.00 per year for 24 books, brimful of choice, up-to-date information.

Are You an Advertiser in "Power House"?

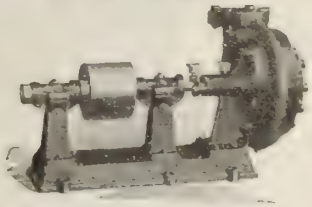
AMERICAN-MARSH PUMPS

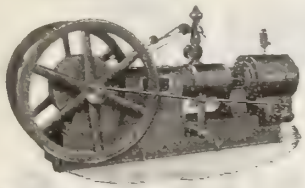
SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors

Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

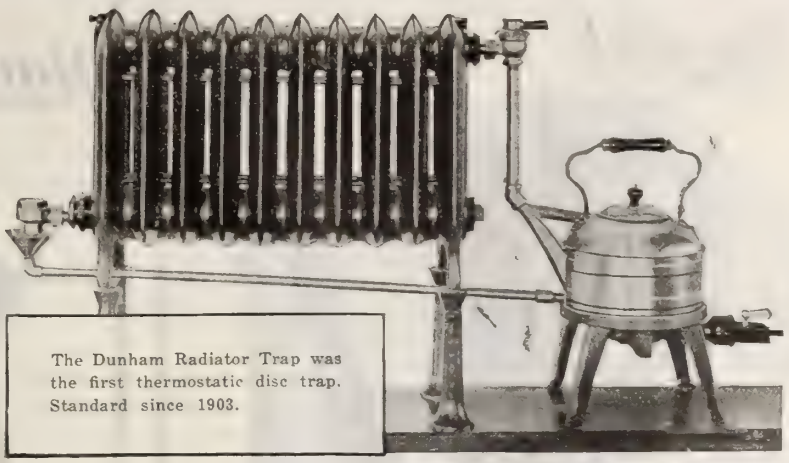
Heating a radiator with a teakettle

It was done at the Ottawa Technical School before a group of engineers who were amazed at the demonstration. It proved beyond question that low pressure steam will quickly heat a radiator to 100% efficiency if the trap is right. It undisputably proved that the Dunham Radiator Trap functions perfectly.

Since 1903, the Dunham Radiator Trap has been eliminating any chance of trap trouble in thousands of installations. It was the first thermostatic disc trap. Think of this when you think of traps, and remember that the Dunham Trap is only one element in Dunham Heating Service. The entire service offers much to the man who plans, sells and installs the heating system—and more to him who pays the bills.

If you welcome suggestions that do not obligate you, get in touch with our nearest office. For authoritative information, write for booklet, "Data on Dunham Heating."



The Dunham Radiator Trap was the first thermostatic disc trap. Standard since 1903.

FAIRBANKS-MORSE
EVERYTHING MECHANICAL

This 18-inch Spartan Double Belt was installed July 1917 in the plant of the Western Malleable Co., Beaver Dam, Wis. It has been frequently exposed to steam without injury.

This Husky Belt Stands Steam

STEAM quickly plays havoc with most belts. Not so with this Spartan Leather Belt, which for more than two years has been frequently exposed to this destructive agency.

Why? Because it is made of Spartan Leather—a specially tanned leather which resists exposure to steam, oil, chemical fumes, heat, and other conditions which quickly destroy ordinary leather.

The greater load-carrying power of Spartan is due to its unusual pliability and high co-efficient of friction.

With production costs at unheard-of levels. Spartan's wonderful efficiency is of more interest to you to-day than ever before.

Spartan is one of the Graton & Knight Standardized Series Leather Belts. In that series, there is a belt standardized for every drive. Write for our book, "Standardized Leather Belting."

The advice of our Engineering Department is at your disposal on any power-transmission problem. Ask us questions about belts and their uses and treatment.

Pratt & Cady Renewable Seat Gate Valves BUY THEMSELVES

Every time the seat of a Pratt & Cady "Renewable" wears out—as any valve seat eventually must—the valve really buys itself. For all that is necessary to make this worn valve as good as new is to insert two new seat rings at a cost of a few cents.

You are thus saved the cost of buying a new valve—which would have been necessary had you used an ordinary valve. This saving really pays for your

PRATT & CADY
RENEWABLE SEAT GATE VALVES

The few cents you pay for new seat rings is far less than the cost of removing an ordinary valve from the line.

New seat rings can be inserted in a P. & C. Valve in a few minutes without removing the valve from the pipe line.

Pratt & Cady Valves can be renewed indefinitely. Many are still giving good service after more than a quarter of a century of use.

Made of iron and bronze in all sizes, for all purposes.

You'd be interested in our Valve Book. Shall we send it?

TRADE P&C CO MARK

Advertise for Good-Will

"The last twenty years have witnessed a great development of advertising as a selling force," George Frank Lord, advertising manager of the E. I. du Pont de Nemours & Co., told the Pittsburgh Advertising Club.

"I venture to predict that in the next five years advertising will be recognized chiefly as a great buying force. Instead of using advertising to sell merchandise we will use it to buy customers. For the purchase of good-will it will be classified, even by accountants, not as current expense, but as a long-time investment; a sort of bond that yields dependable interest annually and amortizes itself in ten years, but keeps on returning interest indefinitely.

"If advertisers and advertising men will keep their minds fixed on this idea of buying good-will, or buying satisfied customers, instead of selling merchandise, many of the most difficult problems of advertising will disappear. Appropriations will not be based on last year's earnings, the current year's estimate, the sales department's gross margin, or the tentative impulses of the board of directors, but on clear analyses of the amount and kind of good-will needed for the ideal future of the business, the time required or available to develop it, the total amount it will be worth, and how the expenditure of that total will be made in various years.

"The advertising policy will not be shifted by the weather, the crops, temporary trading conditions or changes in organization. The business itself will have a definite, enduring policy, and the advertising will express it.

"There will be no lying copy, nor merchandise that is made only to sell, and not to use; because such things do not buy customers and are destructive of good-will, the great asset the advertiser is seeking.

"Whether an advertiser formally adopts the policy of buying good-will or not, the good-will value of his advertising is all he really gets for his money. The advertising that buys satisfied customers adds to his good-will, and that which creates dissatisfied purchasers subtracts from his good-will.

"Success is merely the result of having more plus than minus in the good-will account. Since the whole history of advertising proves this is true, why should we not recognize this truth and consciously get in line with it?"

Why Lay Up Fire Brick Again —And have the same trouble year in and year out?

The ordinary brick lining with its joints gives way under the varying furnace temperatures, crumbles and falls down. With Betson's Plastic Fire Brick you can practically eliminate this maintenance of brick work.

BETSON'S REG. U.S. TRADE MARK PLASTIC FIRE BRICK PAT. OFF.

is the pioneer and tried boiler refractory material, and has twenty years of practical experience behind it. Betson's takes up expansion and contraction internally. It is easy to lay up. It forms a monolithic lining without joints and there is nothing to work loose or fall down. It can be used for the entire boiler—furnace, door arches, rear arches, baffles, bridge walls, etc.

Let us quote you on Betson's Plastic Fire Brick for your boiler needs. Or send for our practical booklet to-day.

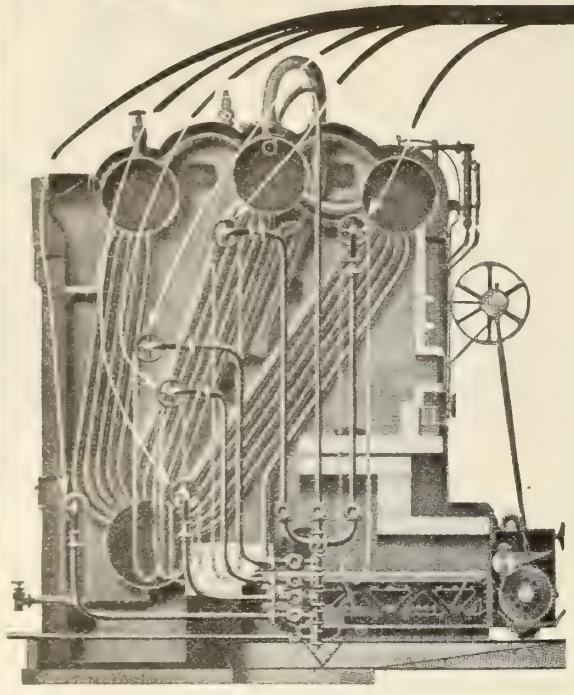
Put Your Water Wheel Proposition Up To Us

6 Reasons



Why this boiler is operated economically

The six reasons are the six Diamond Soot Blower units with which it is equipped. These mean—lowered coal consumption (by 4 to 8 per cent.)—increased boiler efficiency and capacity—decreased use of steam for cleaning—and greatly decreased labor for cleaning.

Diamond Soot Blowers thoroughly remove all particles of soot and fine ash deposit which prevent heat transference (as an insulator soot is five times as effective as asbestos), leaving the tubes clean and free to transmit heat to the water within.

There are hundreds of successful Diamond installations in Canada. Note for instance: Canadian Consolidated Rubber, J. R. Booth & Son, Canadian Locomotive, St. Lawrence Sugar Refining. Goldie & McCulloch, Toilet Laundry, Howard Smith Paper Mills, Montreal Tramways, Riordan Pulp and Paper, Ford Motor, etc.

If your boilers are not equipped write for full information, requesting Bulletin 280.

Buyers and Sellers of New and Used Machinery

A CONTINENT-WIDE SERVICE

TRIMO

THE WORD TRIMO

Stands for good tools made by the Trimont Mfg. Co., which are the following:—

The Trimo Pipe Wrench
The Trimo Chain Pipe-Wrench
The Trimo Monkey Wrench
The Trimo Pipe Cutter (Hand)

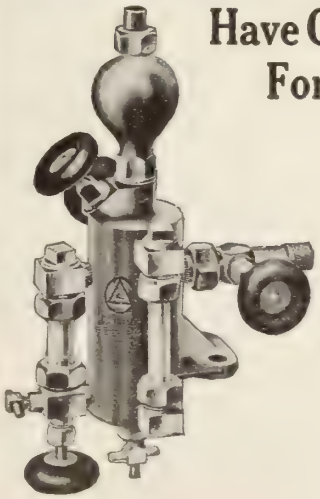
The four good points that make **Trimo Pipe Wrenches** superior are the **Spiral Spring** always in place—**Steel Frames** that will not break—**Nut Guards** that protect adjustment nut—and the **Inserted Jaw** in handle that can be replaced when worn—**Save Money** and buy Trimo goods, made by

Trimo Mfg. Company

Roxbury (Boston,) Mass.

Detroit Lubricators

Have Given Satisfaction For Forty Years.



Built in a sufficient variety of styles to lubricate properly every type of steam engine, pump, gas engine, air compressor, etc.

Send to-day for catalog L 1. The information on lubricating devices contained in it will be valuable to you.

THEIR efficiency holds over half the world's trade.

Makers of Stewart Carburetors.

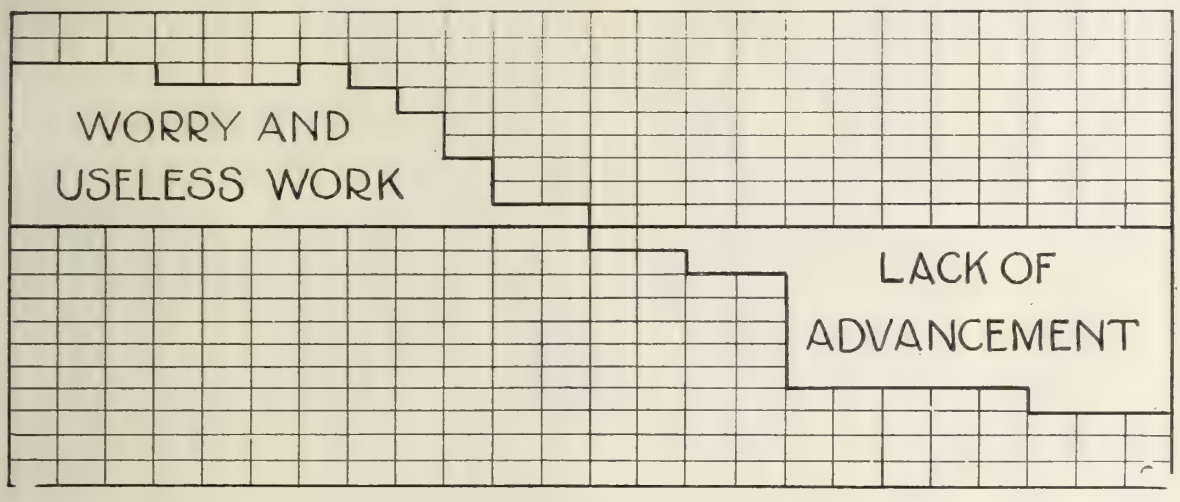
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

We're "Bulls" *on* Canada

PROSPERITY, rising stock values and a vast amount of "Loose" money,—all these have led to the biggest year of speculation Canada has known—1919. The trading in Montreal exceeded all previous records, and "Everybody's doing it." Stenographers and bank messengers are making a few dollars; financiers and plungers are making their millions. And, don't you forget it, many are losing, too.

In this leading article in the February 1st MACLEAN'S the mania for "taking a chance" is discussed and R. Laird Briscoe tells why there are not many losers—yet. Two men have made $6,600,000—this article tells how simply it's done. One typist bought a $2000 car with a $100 bill. It's really very simple when you know how—**IF** you guess right.

J. K. Munro Says:

THERE will be an election before Fall—it's among the probabilities. Sir Robert Borden took the Premiership with him to South Africa. What will he do with it when he returns? Why didn't he nominate a successor before he left? Why could Sir Thomas White have the job if he wanted it, and why wouldn't he make a good leader to go to the country?

These and other questions are discussed and answered in Mr. Munro's snappy, vigorous, pithy style.

Balking the Bolsheviks

A CANADIAN woman had some extraordinary adventures in Roumania with the Bolsheviks. She is Mme. Pantazzi, and was Miss Ethel Greening, of Toronto. She tells how she and her husband escaped death's door by the narrowest of margins—not once but several times. Incidentally, she tells more of the wonderful adventures of that Admirable Crichton of cosmopolitan free-lances, "Klondyke" Boyle—also Canadian as MacLean's readers know.

Flaherty of Belcher Island

THIS is where the natives wear duck feather kimonas, in a part of Canada which even the geologists and explorers didn't know existed until a few years ago. Of course, you would expect the discoverer to be an Irishman—and in February 1 MACLEAN'S you can read how Flaherty found his island, and what he discovered there—the richest iron ore deposit in the world, but—can it be transported to market?

Other Features are:

"Breed," by Archie P. McKishnie.
"The Thread of Flame," the Basil King serial.
"His Majesty's Well-Beloved," the concluding instalment of the Orczy serial.
"Canada Has a Movie Future," by Allan Dwan.
"Spanish Doubloons," more of Camilla Kenyon's rollicking adventure story.
"Mr. Phipps of the 'Old Firm'," by A. Appleby Terrill.

MACLEAN'S is issued Twice-A-Month

starting with this issue. An important point to remember. If you want to keep up with things **nationally Canadian,** you'll have to get the MACLEAN'S Twice-A-Month habit.

Over 350,000 Canadians Read

MACLEAN'S

Showing ease with which Plibrico is laid in place.

PLIBRICO

A High Grade Refractory for Furnace Linings.

BETTER THAN FIRE BRICK

for furnace linings, baffle construction and repairs.

1. It's Jointless.
2. It's Plastic.
3. It's air and gas tight.
4. It will stand 3100 deg. F.
5. It will save fuel.
6. It can be installed by inexperienced labor.
7. It will outlast fire brick.
8. It can be used in any boiler, furnace or oven.
9. It can be used wherever fire brick is used.
10. It cannot be excelled for patching broken and burned out linings.

Any Engineer can see the economy and advantage over Fire Brick. Shipped in steel containers only. Warehouse stock carried in principal cities for immediate delivery.

Write for book on furnace building.

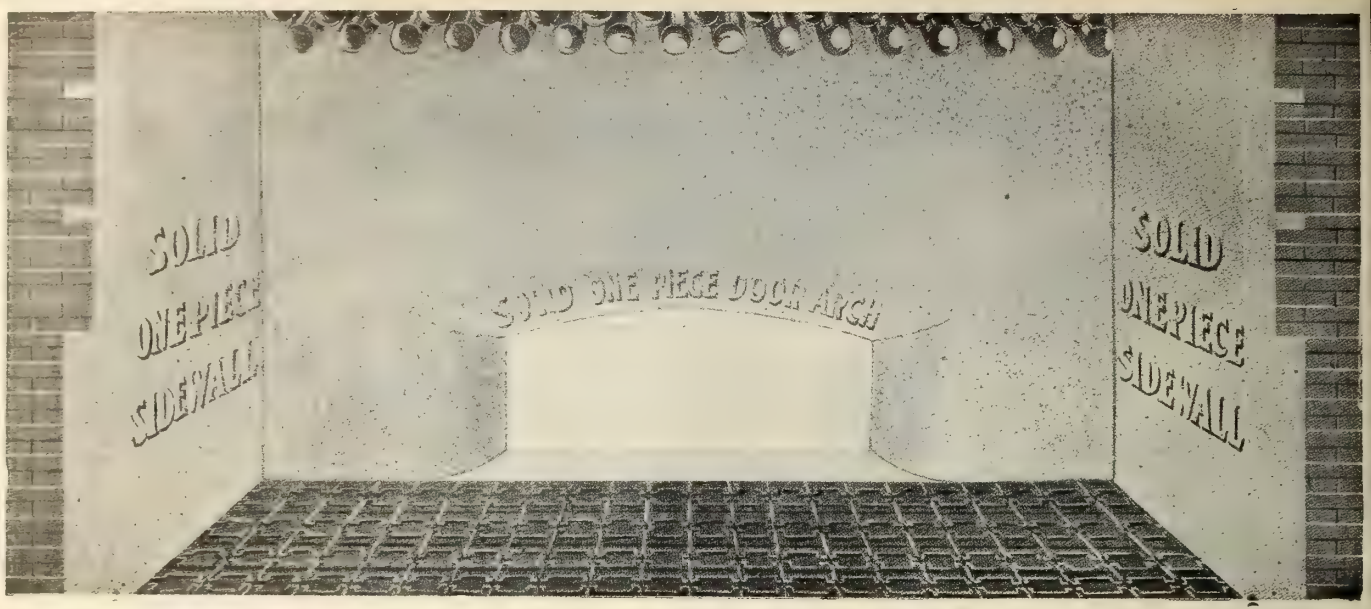
PYRO-PUTTY

TRADE MARK REG U S PAT OFF

FIRE BRICK IN PUTTY FORM

The World's Best Furnace Lining Material



Sketch above represents the fire box of a water tube boiler lined with PYRO-PUTTY

PYRO-PUTTY should be used for building Door Arches, Side Walls, Bridge Walls, Baffles, Rear Arches, Curved Stoker Arches, Dutch Ovens and complete furnace linings of every description.

PYRO-PUTTY is superior to Standard Fire Brick of the highest quality **because** it can be installed **all in one piece**, instead of there being several hundred separate bricks and several hundred joints.

PYRO-PUTTY comes to you in a stiff moist, pliable, "ready to use" condition. Simply pound it in with a mallet and smooth it off with a trowel and the job is done.

WHEN A WORN FURNACE LINING IS PATCHED WITH PYRO-PUTTY THE PATCHES INVARIABLY OUTLAST THE BALANCE OF THE LINING

Repairs to your present fire brick linings can be made at a considerable saving of time and at less expense than would be possible with standard fire bricks.

PYRO-PUTTY is put up in barrels weighing 700 lbs. each NET WEIGHT. A barrel is equivalent to 100 standard fire bricks.

Why not order a few barrels now? You'll soon want more because PYRO-PUTTY always makes good.

Write to-day for further information and prices

"A few barrels of Pyro-Putty should be part of the emergency equipment of every steam power plant"

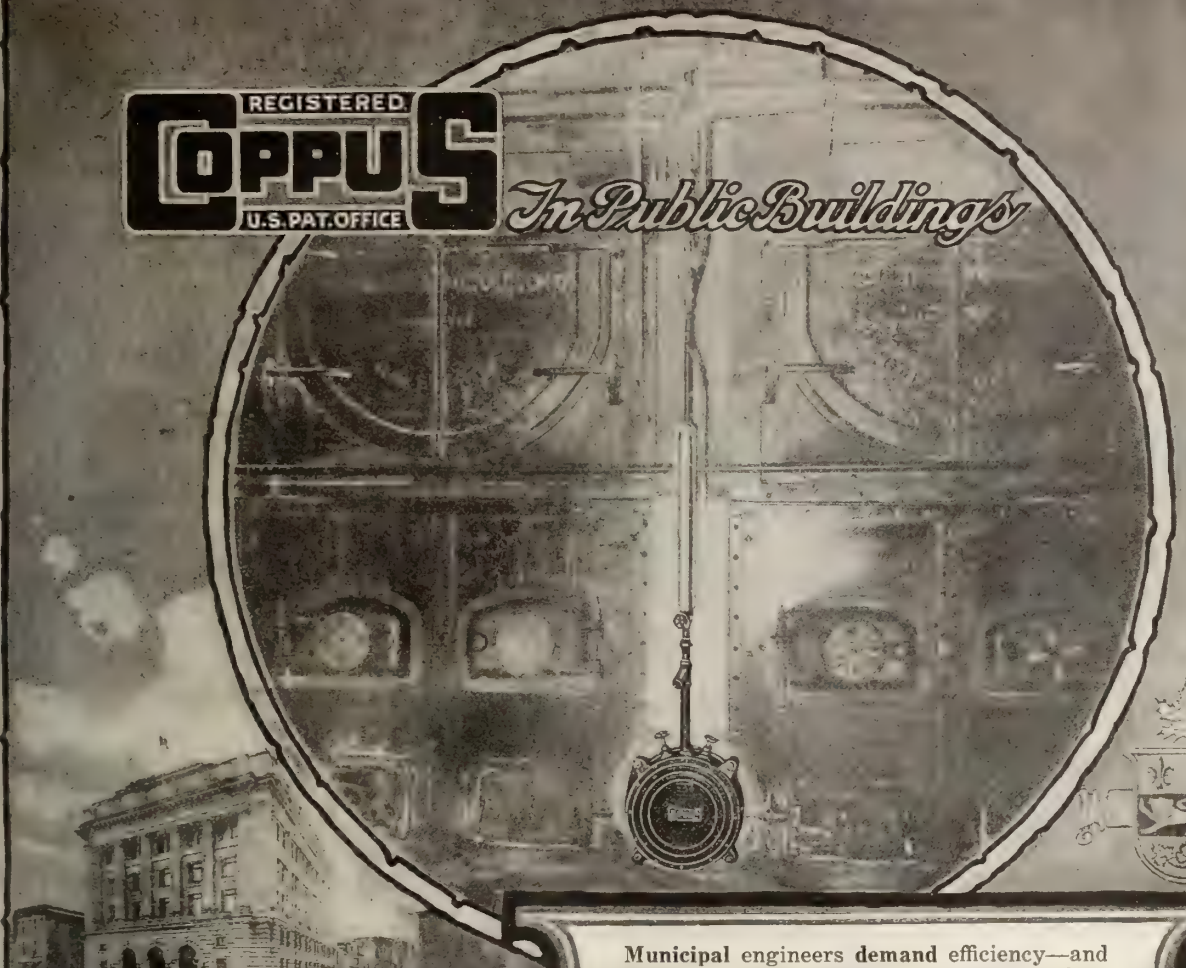
In Public Buildings



Municipal engineers **demand** efficiency—and **insist** on economy of operation. Power plant equipment, to secure the approval of public engineers, must measure up to the **highest** standards.

This 22" COPPUS Turbo Blower in the City Hall at Montreal, Canada, has been burning bird's-eye with economy, and holding steady steam pressure without difficulty for many months. Here, as in thousands of plants the world over, COPPUS Blowers burn cheap coal, save time, labor and money, and greatly increase plant efficiency.

That COPPUS Blowers are recognized as leaders in their line is evidenced in the fact that three-fourths of all the blowers made in America bear our trade-mark. Ask our engineers to show you how "COPPUS Equipment can save you money." Write for Blower Catalog.

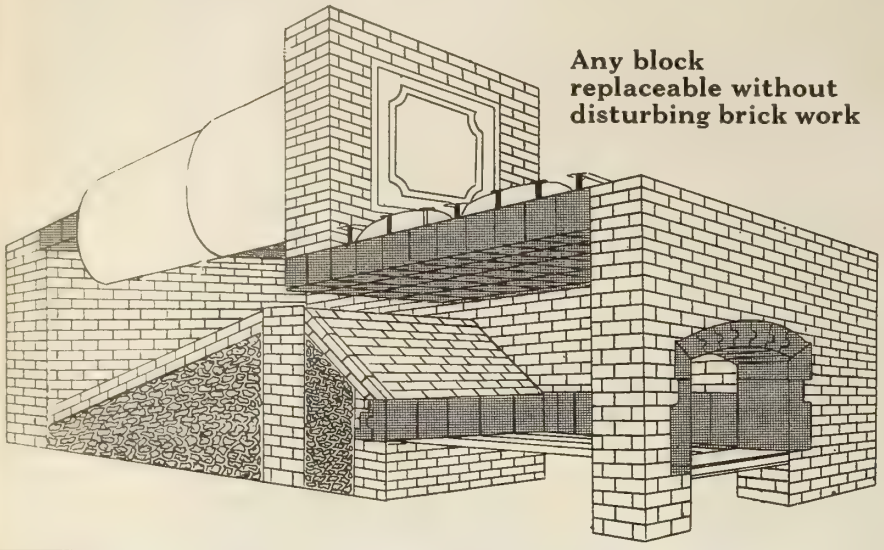
COPPUS TURBO BLOWER

GATES Patent Furnace Linings



FOR REDUCED BOILER ROOM UPKEEP

Made from our specially shaped fire brick of the finest quality, with close-fitting joints that offer no projections for the formation of clinker and greatly reduce the possibility of costly air leaks through the setting.

A handy man can renew any one of the interlocking blocks without disturbing the brick work. The fuel economy and saving in furnace upkeep will quickly pay for an installation.

Specialists in all kinds of power plant brick work. Catalogue on request.

Every Ounce of Energy

AMONG the most important factors in keeping production up and operation costs down is the efficient transmission and utilization of every ounce of energy developed by power-generating machinery. A high friction load means a corresponding reduction in the power available.

The burden of this rests entirely on the correct lubrication of every machine, axle, pulley and shaft. *Nothing but scientific lubrication throughout your entire mechanical equipment will enable it to contribute its full quota to the success of your business.*

Imperial Lubricants are specially designed for each type of machine under actual service conditions. Their use will bring increased income through greater production, and reduced expenses through smaller depreciation of machinery.

Imperial Lubricants are prepared with infinite care. Each one has real merit as its recommendation. There is the proper lubricant for every individual part of your machinery. They are Canadian made, and their high, uniform quality is assured by the use of only the finest crudes.

Imperial Lubrication Engineers will be glad to consult with your own engineer or mechanical superintendent in deciding the proper lubrication of your machinery. The benefit of their knowledge and experience is yours without charge or obligation.

TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Performance Facts of Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all types.

One Standard material for all gasket work—Sold on a Service Basis

DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

STEAM TURBINES

Uninterrupted performance for eight or ten years without a cent's worth of repairs is not unique for these turbines. It is an actual fact that *they do* give continued satisfaction with minimum upkeep. The solid rotor, integral nozzle and reverse buckets, independent emergency valve, and accessible bearing adjustment device are a few features which keep your engineer unhampered with breakdowns. You cannot well ignore investigating the reasons why these turbines are so well thought of by thousands of satisfied users.

No Stoker is Better Than its GRATES

MURPHY AUTOMATIC **FURNACES**

Back of every feature of MURPHY GRATE construction are *many* sound reasons. Consider how these features save you dollars—in fuel—in labor—in maintenance.

The long — narrow — but deep sections give eighteen to twenty-eight square inches of cooling surface to every inch of exposed grate surface.

The liberal air space (47% to 52%) gives double the capacity of the boiler "without one penny for draft."

The correct proportion and distribution of ribs on the stationary grates, combined with the greatest accuracy of machine moulding have solved the sifting problem

The continuous movement of the ribless grates ¾" above and ¾" below the surface of the stationary grates—breaks up the fuel bed — prevents avalanching — keeps the grates clinker-free — and advances the ash gradually to a point where it is removed by the clinker grinder. It is this action that gives the Murphy Furnace the faculty of ***burning anything that has heat in it.***

Yet with all these advantages, the Murphy Grate of to-day is built to the same policy that has characterized every improvement. First, to make all parts standard; second, to make every piece interchangeable; third, to advise users of new developments so that they may keep their equipment up to date—and operating at top notch efficiency.

For information on the Riley Underfeed Stokers for large boilers, see February 5 advertisement or send for Riley Stoker catalog HR-2.

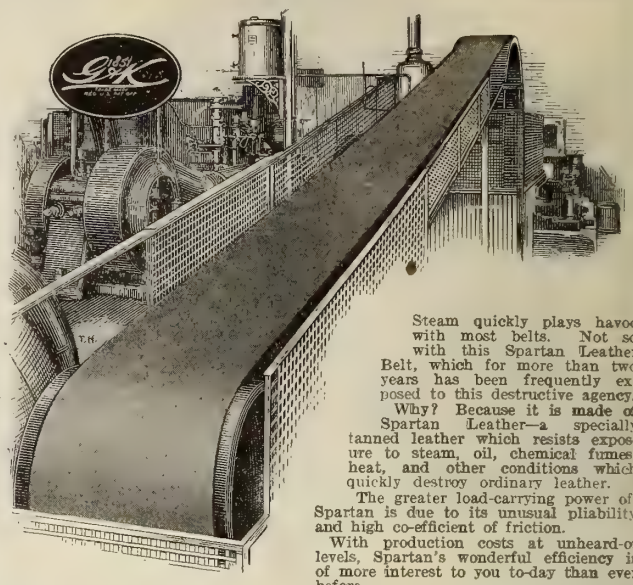
LEONARD

THIS HUSKY BELT STANDS STEAM



This 18-inch Spartan Double Belt was installed July, 1917 in the plant of the Western Malleable Co., Beaver Dam, Wis. It has been frequently exposed to steam without injury!

Steam quickly plays havoc with most belts. Not so with this Spartan Leather Belt, which for more than two years has been frequently exposed to this destructive agency.

Why? Because it is made of Spartan Leather—a specially tanned leather which resists exposure to steam, oil, chemical fumes, heat, and other conditions which quickly destroy ordinary leather.

The greater load-carrying power of Spartan is due to its unusual pliability and high co-efficient of friction.

With production costs at unheard-of levels, Spartan's wonderful efficiency is of more interest to you to-day than ever before.

Spartan is one of the Graton & Knight Standardized Series Leather Belts. In that series, there is a belt standardized for every drive. Write for our book, "Standardized Leather Belting."

The advice of our Engineering Department is at your disposal on any power transmission problem. Ask us questions about belts and their uses and treatment.

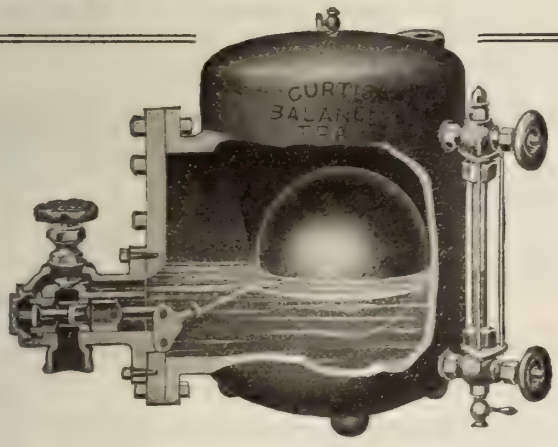
CURTIS Engineering Specialties



Five Superior Features of the Curtis Trap

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on pressure varying from one to 250 lbs.

Write for 1919 Catalog of Curtis Engineering Specialties.

Maintain the Correct Pressure

Don't Waste Power and Don't be too Economical

The TAG Self-Operating Pressure Controller, if applied to a manufacturing process, as illustrated, or to any steam, air, or hydraulic power main, will control the pressure automatically without attention on your part.

The TAG Controller will throttle a 150-lb. pressure down to any desired point below 70 lbs. and maintain that pressure day and night until the power is shut off.

Doesn't that mean a big saving to you in fuel, power and labor? Isn't it worth investigation?

Investigation is easy. Our Bulletin PP-388 describes the TAG Self-Operating Pressure Controller. Our service is at your disposal.

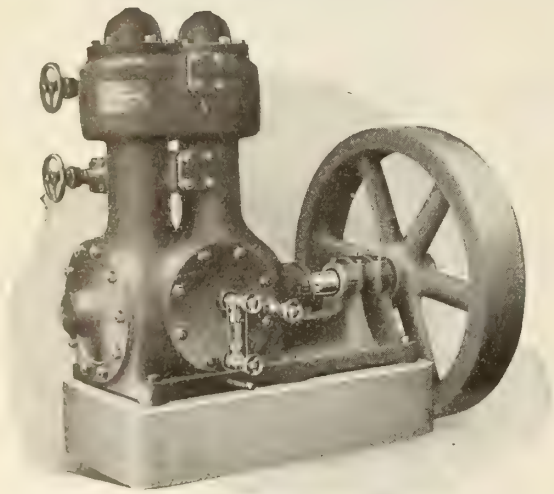
Mechanical Refrigeration



BETTER Than Ice

When saving in operating cost and saving in foodstuffs are taken into consideration, the superiority of **MECHANICAL REFRIGERATION** over refrigeration by ice is beyond comparison.

But any Refrigerating Plant, to be a success and, therefore, profitable to its owner, must be properly designed and installed to meet existing conditions.

Refrigerating installations by the York Organization are based on over 30 years' experience in building Refrigerating Machinery exclusively.

From the standpoint of service, economical operation, low upkeep cost and small amount of attention required, York Enclosed Refrigerating Machines are the best available.

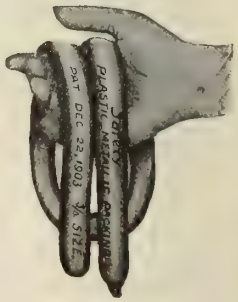
AGENTS WANTED

Practically Frictionless



In Cotton Tubes

—for every purpose

WILLIAMS' Superior Drop-Forged Wrenches are made in nearly one thousand sizes with openings from 3/16 to 7⅝ inches (4.8 to 194 mm.)—"a Wrench for every purpose." And every one is the product of drop-forgers with nearly half a century's experience behind them. That's why *good mechanics* invariably prefer Williams' Wrenches.

Williams' Drop-Forged Wrenches

Dominion Belting Company, Limited
Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal

You Know You are Safe

When "SAFETY-FIRST" SEXTON tackles your—

FIREBRICK WORK

Sexton Boiler Settings are seen in some of the most important plants in Toronto. Names of these plants on request. Ask them what they think of "Safety-First" Sexton's work.

NONPAREIL

Shaking and Dumping Grates Save Fuel

Do you want to save 10 per cent. of your fuel expenses? You do this without a doubt. Prove it for yourself by putting NONPAREIL Shaking and Dumping Grates in your furnaces on a 30-day trial basis—write for the details.

For Grate Bars and Repairs see Sexton

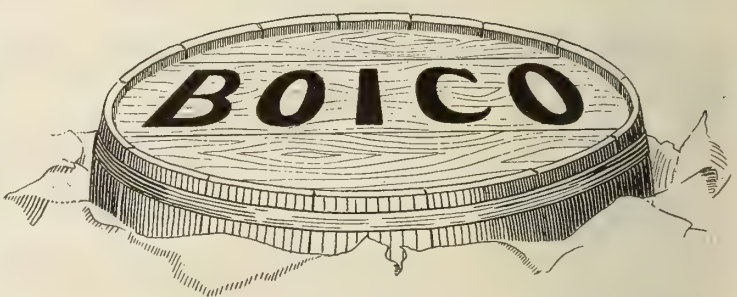
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Better Jobs— Bigger Salaries

Let These Men Show You How to Get Them

Are you interested in sure and rapid advancement to a really worth while position in one of the best paying professions in the country today? If you are it will pay you well to read this announcement. It tells how you, with or without previous training, can prepare yourself in a short time for an attractive position that insures a lucrative salary and an assured future.

Remember—this profession is a new one—unlike all others, it is still uncrowded—and the demand for trained men far exceeds the supply. That's why your services will be in demand when you have acquired the necessary training. That's why you can count every effort a sure and wonderfully profitable investment.

Easy to Learn— No Experience Necessary

In most professions, to become proficient, long periods of intensive study, followed by years of hard training, are necessary. In this new profession—Combustion Engineering—the necessary training can be acquired in a few short months. Why? Because all the knowledge and experience—all the scientific research and experiments—all the labor and study of seven of America's leading Combustion Engineers have been condensed and classified to such a remarkable extent that what formerly required years of study can now be learned in a fraction of that time.

This training from the very first can be applied to the practical every-day problems of any power plant. At some point in the course you must spend some time in power-plant work if you have not already had the experience. That may prove to be your field or you may make it the stepping stone to an executive position. In either case your services will increase in demand and value as you progress in the training.

America's Leading Combustion Engineers Teach You

On this page are photographs of our educational staff. Probably you know some of these men personally. At least, all or most of them, are known to you by reputation.

Jos. W. Hays is the author. His reputation as a writer on Combustion Efficiency is world wide. In this course he has surpassed himself. Every lesson, every chapter, is written in such an interesting, comprehensive way, that the reading of the course is as pleasant as it is profitable.

Associated with Mr. Hays as reviewing and advisory editors are **I. E. Moultrop, W. L. Abbott, Jos. Harrington, Fred R. Low, David Moffat Myers, Prof. S. W. Parr and Arthur L. Rice.** These names alone are proof positive of the thoroughness and completeness of the course.

Especial attention has been given to make this course easily understood by everyone. It is stripped of all unnecessary technicalities and is written in a way that you can quickly grasp and understand. It is prepared especially for the man on the job—the busy man in office or boiler room who can commence putting his knowledge into practice the moment he starts the course.

Send for this FREE BOOK—TODAY

To enable you to get a better idea of just what this course is—just what it covers—why it is a guide to a better job and a bigger salary—why it enables *you* to cash in on the big salary awards that fall to the Combustion Expert—to make all these things clear to you, we have prepared the book "Opportunities for the Combustion Expert." Send for a copy of this book today. It's free.

Mail the Coupon

Simply fill in the coupon and mail it to us. We'll send you a free copy of "Opportunities for the Combustion Expert" by return mail. Time is valuable. Get started today while the opportunities are greatest. Mail the coupon—Now.

An Explosion Pump in Irrigation Service

The Direct-Acting Explosion Pump Contains no Pistons or Other Reciprocating Mechanism Beyond an Oscillating Column of Water Upon Which the Gaseous Products of Combustion Act

THE accompanying illustration, Fig. 1, and drawings, Figs. 2 and 3, show the gas producer plant and the details of construction of the gas producers of Akerlund design, while the arrangement of the direct-acting explosion pump in irrigation service at Del Rio, Texas, may be noted in drawings, Figs. 3 and 4. This first installation in this country of a large six Humphrey direct-acting explosion is used by the G. Bidell Moore estate for the irrigation of a tract along the Rio Grande, of twelve thousand acres.

The Moore Estate has purchased Humphrey pumps and Akerlund-type producer for wood and coal burning. The pumping station is located some 15 miles by road from Del Rio, the nearest railroad station. Eagle Pass bituminous coal could be delivered at the plant for $4 per ton, while fuel oil would cost some $2 per bbl. Much of the land covered with mesquite wood will have to be cleared before cultivation, therefore the use of this wood as fuel until clearing was completed seemed attractive and its possibilities in gas producers has been fully investigated with highly satisfactory results.

This explosion pumping station is located directly upon the banks of the Rio Grande River at a point where a rock ledge extends entirely across and creates a slight fall. A forebay is being excavated in the river bed adjacent to the pumping station and just above the ledge. At the downstream end, the forebay is being closed by a small concrete dam and in this is placed a 66-in. circular sluiceway which can be closed in by a 66-inch butterfly valve-operated from the interior of the station.

Normally, this valve will be kept open so as to keep the forebay free of silt deposits, as the river is very muddy. The intake to the pumping station is five feet in diameter. At its outer end it is protected by a screen inclined at a slope of 1 on 3. The Humphrey pump is designed to pump a minimum of 28,000 gal. per min. against 37 ft. though the designers are confident of showing 30,000 gal. on test and the hydraulic works have been designed for the latter figure. The guaranteed thermal efficiency is 20 per cent. when using producer gas of over 100 B.T.U. per cu. ft. The pump and play-pipe are 66 inches in diameter, the latter being 100 feet long. The pump is housed in a reinforced concrete well, 34 feet deep, shown in the accompanying figure, designed, to resist the full hydrostatic pressure of flood waters.

The operating floor is 3 feet above the lowest river level. The water level in the pump well is maintained at constant elevation, irrespective of the river stage, by a float-controlled hydraulic gate valve operated by pressure from the high canal. A gasometer is placed in the gas main leading from the producer to the pump. This, for safety in case of backfires, is a steel tank with the lower end open but sealed by the water in the pump pit.

Also installed in the pump pit is a 1 kw. electric generator direct connected to a small turbine operated by water from the canal, and a two-cylinder air compressor which can be driven either by the turbine or by an explosion engine operated by producer gas or gasoline, also a 3 inch centrifugal pump belted to the gas engine of the air compressor for draining the pump well. The top of the conical roof of the superstructure is provided with a 36 inch exhaust cowl. Fresh air is admitted to the pump pit at the operating floor level through a 24 inch pipe with a top cap designed to force air down by wind action.

The pipe opening into the pit carries an 18 inch motor-driven blower on hinges so as to be swung into place for service when the wind velocity is too low to secure sufficient natural ventilation. The play-pipe discharges into a reinforced-concrete surge tank, 36 x 12 ft. The discharge pipe extends 9 inches above the normal water level in the canal. The guaranteed lift of the pump is fixed at 37 feet; as this is not sufficient to irrigate a tract of some 500 acres in the immediate vicinity of the pumping station, it is intended to use the wave action in the surge tank to raise a small supply canal. The arrangement for this is not shown on the accompanying figure.

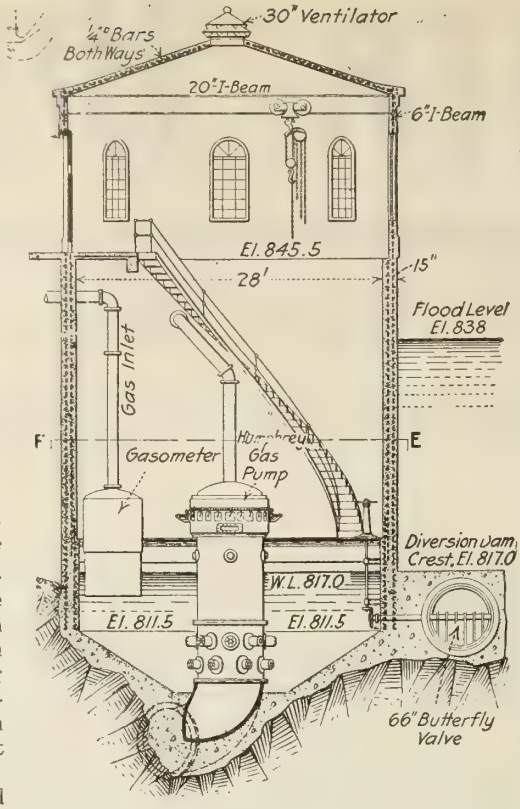
The surge tank is also designed to act as a grit chamber, the grit to be washed into the river through a 18 inch cast-iron pipe. In the operation of the Humphrey-type pump a charge of gas-air mixture is exploded in

FIG. 1. GAS PRODUCER PLANT FOR EXPLOSION PUMP

a chamber above the water surface, no piston being used. The explosion drives the water downward, closes the water inlet valves and sets the whole water column in the play-pipe in motion. The inertia of the moving column of water permits the burned gases to expand below atmospheric pressure when both exhaust and water valves open. There follows a return source of the liquid column until the water reaches the exhaust valves and closes them by impact.

There is a second forward surge set up by the trapped compressed gases and when the pressure again falls below atmospheric a fresh charge of gas and air is drawn in. This is finally compressed by the second return surge and exploded, when the cycle repeats. The inlet and exhaust valves are interlocked so that the proper sequence of operation is maintained. In the American Humphrey designs the complicated arrangement of rods and bell cranks by which the interlocking is accomplished on the large Chingford pumps in England, has been superseded by a simple sprocket chain thrown around the valve belt, engaging valve-arm studs and moving a short distance first in one direction and then in another to shift the lock from one set of valves to the other.

It is of interest to note that the period of oscillation is about proportional to the square root of water-column length; in this case the pump will have approximately 12 cycles per minute. There are two types of ignition equipment, jump-spark plugs operated from storage batteries and coils, and "wipe spark" or arc igniters taking current from the turbine-driven generator. To start, an initial charge of gas and air will be forced in by compressed air, all the valves being held shut. After explosion the play-pipe oscillations thus initiated are strong enough to work the valves.



4. IRRIGATION EXPLOSION PUMP, MOORE ESTATE, DEL RIO, TEXAS

The gas-producer plant noted in Fig. 1 is of special interest located very close to the pump house on higher ground and it comprises a vertical-down-draft generator with a water pan on top and a vapor ring around the combustion belt; air is admitted to the vapor ring and the mixture of air and steam enters the fuel chamber above the green charge. The gas is led off through a spray-cooler, a wet scrubber, exhauster, dry purifier and delivery pipe. On trial runs of the producer with mesquite wood, it was found that the average wood burned per hour was 436 lbs., the average gas made per hour being 23,850 cu. ft. and the average gas made per lb. of wood was 54.7 cu. ft. The average b.t.u. per cu. ft. of gas was 114.5, the average wood per sq. ft. of fire area being 20.8 lbs., and wood per horsepower hour used was 1.76 lbs. The details of construction of the Akerlund gas producers may be of interest.

The Akerlund gas producer noted in Fig. 2 operates on the up-draft principle under pressure. A steam jet blower supplies steam and air from below in the proper proportion and this mixture, as it passes through the fire, supports the reaction which result in the combination of fixed gases known as producer gas. The producer shell is a simple steel cylinder resting in a cast iron ring, built in sections, which is supported on piers in a water-seal. The ring projects into the water, forming the seal, and ashes are removed through water around the lower edge of the ring without any escape of gas and without interfering with continuous operation. The shell has a straight lining of standard firebrick; in diameters of eight feet or larger, these

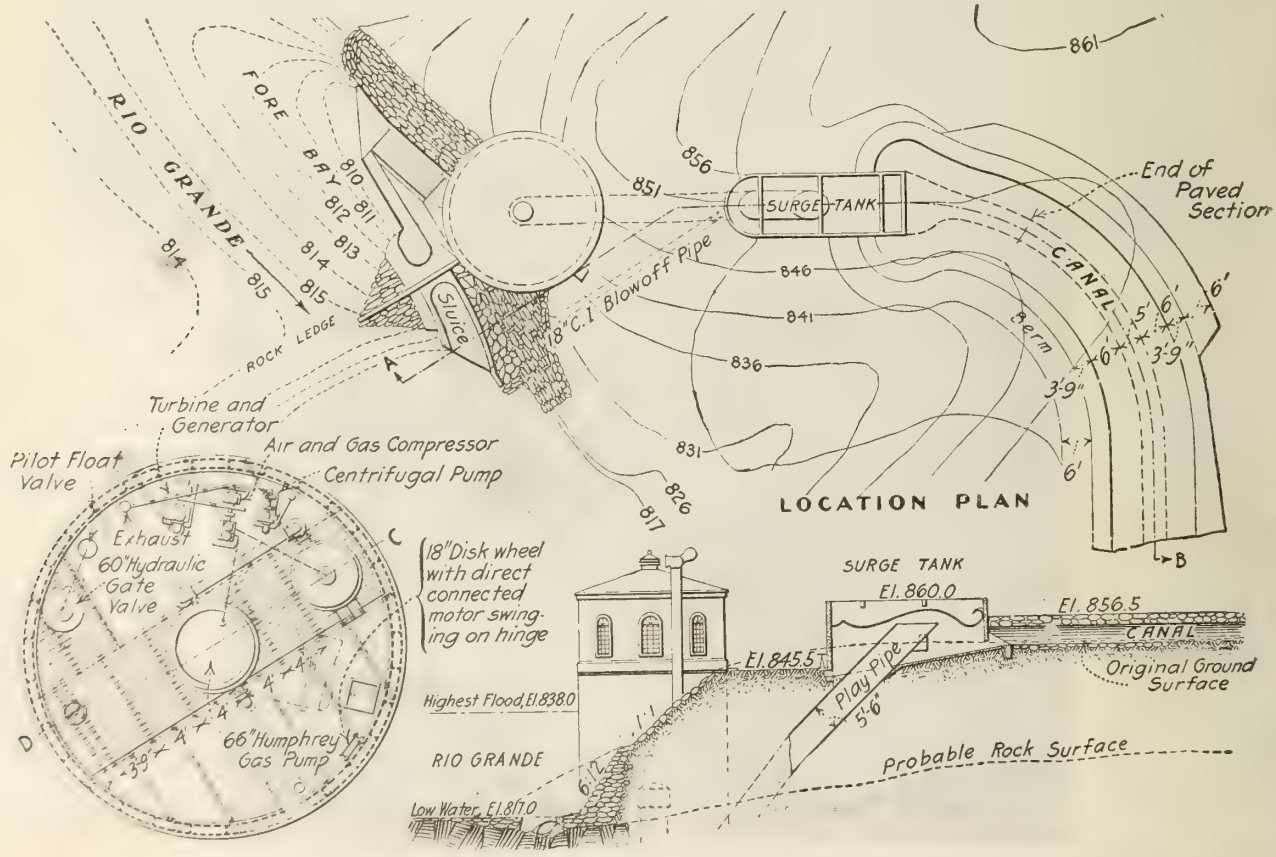


FIG. 3. PLAN OF IRRIGATION EXPLOSION PUMPING STATION

bricks are arched slightly to the centre at top to project as far as the central water-cooled section.

The lining has no slopes or projections which might serve as a lodging place for clinkers and ashes and thus cause bridging, which is a serious trouble with improperly designed gas producers. The

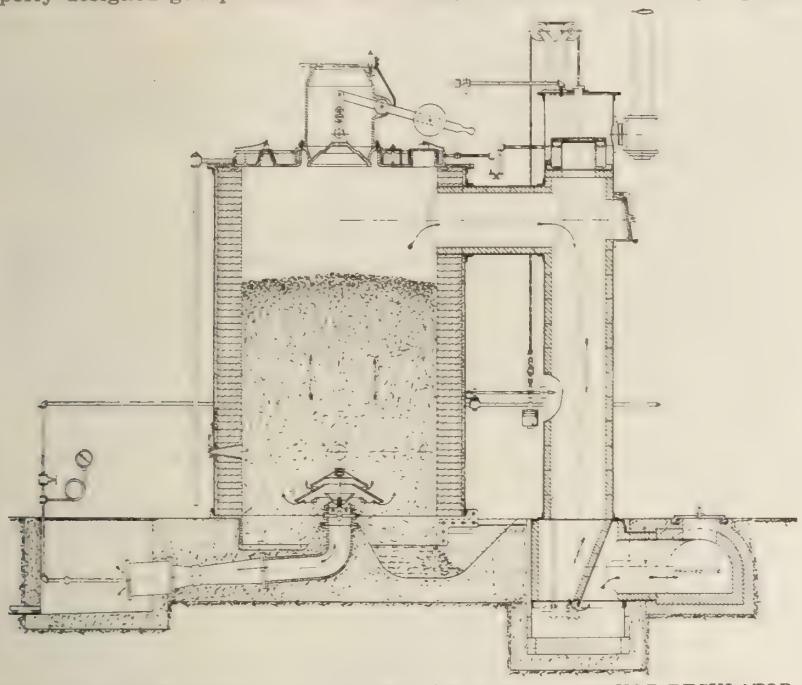

FIG. 2. GAS PRODUCER OF TYPE WITH AUTOMATIC PRESSURE REGULATOR

blower is designed to deliver the proper proportion of steam and air in the blast.

It is maintained that the efficient operation of a gas producer is dependent upon the even distribution of the blast through the fire. To promote ideal conditions in this respect, the blower discharges through a blast hood built in sections, larger diameters requiring more sections than the smaller sizes. Thus blast hoods are built up from the same set of castings and the sections overlap to prevent clogging by ashes or clinkers.

The water-cooled top plate is built of cast iron in sections and the outer ring consists of segments bolted to the top angle of the producer shell. The central water-cooled section of the top is a solid casting, which rests in this ring. This makes a self-supporting top, which is entirely independent of the brick lining. Gas producers which support the central water-cooled section of the top plate entirely on the brick lining are subject to troubles when the lining begins to deteriorate. The top plate remains in good condition indefinitely, and by a slight addition to the first cost of the plant greatly reduces the cost of repairs and prevents the possibility of serious leaks in case the brick lining should settle or give way even slightly.

It will be noted that the charging hopper is of the double-valve type, distributing fuel by dumping through an opening made by lowering a bell. This has proved to be the simplest method of supplying fuel to the fire and distributing it evenly over the surface of the fuel bed. The capacity of the hopper is the same as the consumption of the producer for a certain period, usually from one to two hours, so that reasonable care to charge fuel for periods of corresponding duration will give all the advantages of continuous automatic feeding.

There is a central gas off-take for large units mechanically operated in capacities from 500 h.p. up. The gas is taken off through a hood, centrally located below the fire. In addition to the supply of air and vapor which is introduced above the fire, there is a secondary supply of air and vapor which is introduced through a number of tuyeres set in the brick lining just below the coking zone.

The path of this secondary air and vapor is from the perimeter of the fire downward and radially to the central gas outlet. In connection with the supply of air and vapor introduced above, this insures uniform combustion throughout a comparatively large area and makes it possible to build this form of gas producer in units beyond the usual limit. The air and vapor supply for the central off-take design is automatically regulated.

CROSS EXAMINATION

A reader sends an old newspaper cutting containing an amusing travesty by "S.L.H." of a cross-examination. The scene is a coroner's court in some hole-and-corner country town which has sprung into notoriety by reason of a railway accident. The general manager of a big company has been brought down and is giving evidence:

Coroner: "I take it that you have some knowledge of railways?"

Witness: "I have had daily experience in railway affairs for more than 50 years."

Coroner: "Then you probably know the difference between a locomotive and a cattle truck?"

Witness: "That is so."

Counsel (feeling that he must say something): "I put it to you that there is a difference between the two?"

Witness: "There is."

Counsel: "A real difference, and not a mere imaginary or theoretical distinction?"

Witness (horribly bored): "Oh, yes; quite a real difference."

It is eventually brought out that "a projection shown on one side of the rim of a wheel" is a flange, and that without flanges on the wheels "the train could not have arrived at the spot where the accident happened. The jury therefore find the flanges responsible for the accident."—"North Eastern Railway Magazine."

PANEL SYSTEM OF COAL MINING

Under the present conditions when the demand for fuel is abnormally high, the extraction of the highest percentage of total coal in the progress of mining is a problem of vital importance. The Engineering Experiment Station, in cooperation with the Illinois State Geologica Survey and the United States Bureau of Mines, has undertaken an investigation of the subject and has made a somewhat elaborate study of the facts and of the compiled information. An investigation of the percentages of coal extracted and lost in Illinois and in other bituminous coal mining districts, showed that the percentage obtained is less than is commonly believed, averaging only about 50 per cent. This conclusion has led to the study of the panel system of coal mining in order to determine the greatest possible extraction with different dimensions of working. Previously other investigations of a similar nature have been made to determine the relation between dimensions of workings and amounts of extraction, but, so far as is known, no study of the panel system in general with regard to the percentage of extraction and the change of this percentage with the change of dimensions of workings has hitherto been made.

The results have been published by C. M. Young, Assistant Professor of Mining Research, in Bulletin No. 113 of the Engineering Experiment Station, Urbana, Illinois.

POWER PLANT RECORDS

One of the most essential things in power plants in the systematic record of operations by daily logs and recording apparatus, and when the results are published on engine room bulletin boards it creates a rivalry between the different shifts and promotes a desire among the men for higher efficiency. The importance cannot be overestimated. In this way affairs in the plant are lifted from the realms of guesswork to certainty. While the systems adopted for ordinary plants may be simple, the records should be arranged for convenient reference so that comparison of results with past performance may be made. Thus it is possible to note the effects of changes in equipment or improvements in economy, or the reverse, may be at once detected.

The General Fuel Situation in Canada

The Commission of Conservation, Ottawa, in Their Report on Pulverized Fuel, Gives Some Interesting Data Relative to the Fuel Situation in Canada. The Following Article Presents This Material in Abstract Form

IN a country of such enormous proportions as the Dominion of Canada, extending from the Atlantic to the Pacific, and northward to the Arctic, and with its severe winters, the question of an adequate fuel supply as a source of heat, light and power, and for use in the metallurgical industries, must always be of paramount importance. To a great extent the requisites of power and light can be supplied by the utilization of the numerous waterfalls with which the country is so abundantly supplied. Based upon investigations by the Commission of Conservation, the total water-power in Canada is estimated at 18,953,000 horse-power. Assuming that, under average conditions, one horse-power-hour can be produced in a steam plant from three pounds of coal, one-half of the 17,000,000 horse-power, if developed, would, on a basis of twelve hours a day, and a load factor of 50 per cent., represent a saving of nearly 24,000,000 tons of coal per year. Although hydro-electric energy will, where available, to a great extent replace the use of coal for light and power purposes and for certain metallurgical work, the necessary uses of coal will continue on a large scale.

The coal deposits of Canada, in respect of quality, quantity, and accessibility for mining purposes, compare favourably with those of other countries. About one-sixth of the coal resources of the world is possessed by Canada. The deposits are, however, confined to the eastern and western portions of the Dominion, the large central market being supplied by imported coal. Previous to the war, Nova Scotia bituminous coal was used as far west as Montreal, while United States bituminous was sold within the area extending from Montreal to Swift Current and Saskatoon, Sask., the railways being the principal users of this fuel. Portions of Manitoba and Saskatchewan are supplied with coal also from Crowsnest, Lethbridge, Canmore, Drumheller, Edmonton, Yellowhead Pass and Souris districts.

Eastern Canada possesses no deposits of anthracite, and, as this class of coal is suitable for heating and domestic purposes, considerable quantites are imported from the United States. Prior to the war, it was sold over an area extending from Nova Scotia to Battleford, Sask., in the west. In 1913, imports exceeded 4,640,000 tons, more than double those of 1906; thus it is apparent that the demand for anthracite is rapidly increasing, notwithstanding the upward tendency of prices. The supply of anthracite coal in the United States, also, is limited, and there is no assurance that its export to Canada will be long continued. If mined at the present rate, the anthracite coal reserves of United States will be exhausted in about 100 years. We may, therefore, expect the price to gradually increase, until only the wealthy can afford it. Coincidently with the rising price, production will decrease, thus prolonging the life of the mines. Thus, during the four-year period, 1913-16, production decreased from 91,524,922 tons in 1913 to 88,312,000 tons in 1916, or rather more than one per cent. per annum.

Of the total consumption during 1916, 45 per cent. was domestic coal and 55 per cent. imported coal, or, in other words, we imported more coal than we produced. The importance of this fact may be more fully recognized when it is realized that the value of the coal production, in 1916—$38,857,557—greatly exceeded that of any other mineral, and amounted to nearly 22 per cent. of the total mineral production of Canada during that year. Although we have over 17 per cent. of the world's reserve of coal, our production is small, and we import more than we produce.

From the above it is evident that, before many years, Canada may have difficulty in procuring supplies of anthracite coal from the United States, except at a greatly increased cost; also, as we have no supplies of this class of coal east of the Rocky mountains, we cannot supply the need from our own resources. We arrive at the conclusion, therefore, that, to take its place, some kind of substitute, of which we have large reserves, must be developed.

The following conditions have to be dealt with:

(1) Domestic fuel problem in Ontario and Quebec.
(2) Imported bituminous coal used as fuel on railways and as a source of power in Ontario, Manitoba and Saskatchewan.
(3) Domestic fuel problem in Prairie Provinces.
(4) Cheap power problem in Prairie Provinces.

(1) The following solutions of the domestic fuel problem in Ontario and Quebec are suggested: (*a*) By the installation of by-product coke-ovens at certain points on the St. Lawrence and Great Lakes system, the coke being used for domestic purposes in place of anthracite coal; (*b*) by the development of a peat industry, where peat deposits are near the market for such fuel; (*c*) eventually, electric energy will, to a limited extent, replace coal for heating and cooking purposes.

(2) The establishment of the distribution system of the Ontario Hydro-Electric Power Commission has been effective in largely replacing imported coal as a source of power in Ontario by electric energy derived from our water-powers. But for the work of this commission, many industrial plants in Ontario would have been hampered during the war, if not forced to shut down, for lack of power.

The economic solution of the railway fuel problem may be secured by the electrification of our railways which, for obvious reasons, would be undertaken step by step. So far as certain portions of the Prairie Provinces and Western Canada are concerned, the problem may be solved by the use of pulverized lignite or sub-bituminous coal, by the use of briquetted fuel made from lignite or bituminous coal, and by the increased use of our own bituminous coal, which is equal in every respect to that imported.

Consideration of this problem of importing coal requires that it be discussed under two headings, *viz.*: "Anthracite Coal" and "Bituminous Coal."

Anthracite Coal—This domestic fuel is a luxury, not a necessity; the higher grades of sub-bituminous and lignite coals can be used in its place, and have several advantages over hard coal. In 1918-19, for the first time, Winnipeg used western coal to a very considerable extent, and it gave good satisfaction, notwithstanding the fact that most people were not familiar with the manner in which it should be used.

Bituminous Coal—The imported bituminous coal is used largely for railway use, but a portion is also used for ordinary power purposes.

The value of the imports of coal into Fort William, Port Arthur, and Manitoba ports of entry amounts to from $14,000,000 to $18,000,000 annually. This figure represents actual money that goes out of the country. This money would otherwise be spent in developing Western Canadian industries.

The problem, which must be solved, is briefly this: How can Canadian coal be used in place of imported coal, without costing the consumer more, and at the same time solve the transportation problem? The answer to this problem and the putting of it into practice will mean twice the number of men employed in the coal mines in the west, and, at the same time, retaining in the country the large amount of money above mentioned.

The coal mines of Alberta and Saskatchewan have a capacity for producing some 15,000,000 tons of coal per annum. This fact is of importance when it is considered that the actual production of coal in these provinces in 1918 did not exceed 6,319,663 tons. There is no doubt, even under existing conditions, but that the production could be increased some 4,000,000 tons if the demand should warrant it.

The enlargement of the markets for western coal would also be the means of reducing the price of this coal to the consumer. For example, practically all the domestic coal-producing mines in Alberta are closed down from March 1 to August 15, which means that the fixed charges during this period must be borne by the coal produced during the autumn and winter.

Actual operation shows that, in the same time, operating at 50 per cent. capacity as against 85 per cent. capacity, the cost of production per ton of coal amounted to over $1.10.

This situation could be improved by the Government carrying out the recommendation made by the Conservation Commission that a supreme engineering authority be appointed, with full powers to prevent the use of wasteful methods in the mining of coal; also by the stocking of coal during the summer months.

Under present conditions dealers will not stock coal during these months, owing to additional costs necessary to cover carrying charges, etc. A dealer who stocks coal also has to compete with those who deliver direct from the cars during the winter. There are, therefore, no inducements offered for stocking coal.

In order to secure a more equable distribution during the entire year, and thus relieve the car shortage which occurs in winter, and at the same time permit of the working of the coal mines during the summer months, it appears desirable that special freight rates should be granted on coal shipped eastward during this period and also that the mines should give special summer prices for coal. The differential between the cost of summer and winter coal should be great enough to encourage not only the dealers to stock up, but also to induce consumers to lay in their winter supplies.

It is of first importance also that an investigation be carried out by the Government to determine what special processes could be applied to the more economical use of the low-grade fuels in Alberta and Saskatchewan.

In a report, *Conservation of Coal in Canada*, published by the Commission of Conservation, in 1911, the briquetting of the lignites of the west were advocated to obtain the above conditions. One of the first problems considered by the Honorary Advisory Council for Scientific Research was the possibility of the briquetting of carbonized lignite. Indications point towards the establishment by the Dominion Government, in conjunction with the Governments of Saskatchewan and Manitoba, of a commercial plant to demonstrate the practicability of the process. Should the result be satisfactory, it will not only provide a suitable fuel for the farmers in place of imported anthracite coal, but will cause a great development of the coal-mining industry of Saskatchewan.

Distribution of Imported Coal

As the coal-fields are situated in the eastern and western portions of Canada, the interior portion, from Cornwall, Ont., on the east, to Swift Current, Sask., on the west, is supplied by coal from the United States. The central and eastern portion, comprising central and eastern Ontario, is supplied *via* St. Lawrence, Lake Ontario and Niagara River ports; coal for the west is hauled by rail to Buffalo and Lake Erie ports, whence it is carried by water and rail to its destination. The bituminous coal is used principally for railway and the anthracite for domestic purposes.

The coal brought up the Great lakes is carried as return freight in ships engaged in the ore-carrying trade. Owing to the higher wages paid the miners and higher transportation charges, industries in Canada dependent on United States coal are handicapped. The increase of prices will tend to increase the distribution of Canadian coal farther east and make possible the development of uses for inferior coal.

The most important users of imported coal are the railways and transportation companies.

Railway Fuel

One of the most important factors in locomotive haulage is that of a suitable and economic fuel

The tonnage of coal used annually on railways in Canada is equivalent to nearly 58 per cent. of our total coal production for same period. In 1918 the coal production of Canada was 14,977,926 tons, while in the same year the railways consumed 10,173,344 tons of coal. In addition, 52,507,528 gallons of fuel-oil was used as locomotive fuel. The oil was imported from the United States and represented the equivalent of 312,545 tons of coal.

The development of fuel-oil, for use on railways and steamships, has resulted from the discovery of large oil-fields in California. Oil fuel has many advantages over coal, but its use or non-use will largely depend upon whether it is the most economical fuel under the circumstances. Railway companies have adopted it, not on account of any compulsion on the part of the Government, but from business considerations. On account of the ease with which it can be loaded into boats and fired, and because it occupies less space than coal, thereby giving greater freight-carrying capacity to steamships, it will be used on this class of traffic even after its price exceeds the price of its heat-equivalent in coal.

Fuel-oil has been used to a considerable extent on railways in the United States since its introduction in 1900. The partial exhaustion of adjacent oil-fields has caused some of these lines to revert to coal. The reversion will be still more evident as the increasing prices for oil offset its advantages. The use of fuel-oil in Western Canada will depend upon the low price of crude oil from California or other states bordering on the Pacific and Mexico. With regard to this subject, David T. Day, in *The Production of Petroleum in* 1913, states: "In California the railways were the first to absorb large quantities of California oils. This legitimate use has become permanent from lack of other fuel, and it has extended to other kinds of generation of power, including marine transportation for shipments coastwise and to foreign countries. A *serious menace to the continued use of oil for fuel in California* is the recent change in the character of the crude oils of that state. Many of the new pools yield oils suitable for refining and for the production of large quantities of gasolene and kerosene. Up to the beginning of 1913, about 30 per cent. of the oils of California was refined and the rest was sold for fuel, as crude, or after very slight distillation of the lighter products. This practice changed materially during 1913, so that the proportion of crude oil used direct as fuel became reversed, and, although no accurate figures are available, 70 per cent. is about the proportion of crude oil which was refined during that year, before the heavier portions were sold for fuel. The result of this, however, will be, not to decrease the use of oil for fuel, but to change the method of its application, particularly to the internal-combustion engine burning kerosene and heavier distillates". It is another significant fact that in 1915 the number of producing wells was increased, but the average yield per well per day dropped from 47 barrels in 1914 to 39 barrels in 1915. Although the petroleum business in California during 1915 was poor, and the price of oil one and one-half cents per barrel less, this was due largely to the effects of the war. The price, however, will increase for the above reasons, and there will be a greater demand for it for steamship use, incident to the placing in full operation of the Panama canal. The writer is of the opinion that, in so far as Canadian railways are concerned, the economic advantages of fuel-oil for locomotive use over that of Canadian coal is more favorable now than will be the case in the future. Should this prove to be the case the railways will, no doubt, for economic reasons, revert to the use of coal.

The coal reserves of Canada are considerable, but a large proportion is unsuitable for use in the ordinary way as locomotive fuel. The coals of Manitoba, Saskatchewan, and portions of Alberta are lignite or sub-bituminous, high in moisture, and cannot be used as locomotive fuel on account of the liability of setting out fires from excessive sparking.

In 1913, the Board of Railway Commissioners issued an order calling upon the railways to equip their locomotives with fire-preventive devices, to discontinue the use of certain grades of lignite coal on their locomotives, and to guard against outbreaks of fire along their rights-of-way.

In so far as supplies of fuel are concerned, the eastern portion of Saskatchewan forms the competitive area between the United States coal, on the one hand, and the high-grade bituminous coal of the Rocky mountains and adjacent region, on the other. It is evident, therefore, that the cost of fuel in this portion of the province is high. On account of our large imports of coal and fuel-oil, which, under these circumstances, are costly fuels, anything that can be done to increase the efficiency of generating power from coal or economically curtail the use of fuel-oil by the substitution of coal or lower-grade fuels which formerly could not be used on account of their liability of setting out fires from sparks, should be welcome.

Operating Features of Steam Turbines

The "Travellers' Standard" Publishes Some Interesting Data Relative to the Operation of Steam Turbines, Particularly From the Safety Standpoint

IT WAS only a few years ago that the steam turbine came into marked prominence, yet it is now one of the most important prime movers used in power plants and for the propulsion of steamships. Its rapid development and continued success have resulted from many causes, chief among which (as suggested in an earlier article in this series) are the economy of the machine in steam consumption, floor space, first cost, maintenance cost, and attention. Turbines are now built in sizes that would have appeared incredible ten or fifteen years ago, and advance in this direction has been paralleled, at the same time, by the adoption of much smaller units for minor purposes.

Although the turbine shows high efficiency and has a great many other advantages, it is by no means free from danger, and in consequence of the relatively small amount of experience that operating engineers have had with it (in comparison with the experience they have had with the reciprocating engine) the dangers that are peculiarly associated with the turbine are not always fully understood. The purpose of this article, therefore, is to point out some of the more important operating dangers that are present, and to indicate how these may be avoided.

The thing most to be feared in connection with a steam turbine is the rupture of the rotating part on account of centrifugal force or some other cause, and the bursting of the casing. In either case there will be a sudden liberation of vast quantities of steam. There is also an immense amount of mechanical energy stored up in the rotating parts, just as there is in the flywheel of a large reciprocating engine, and this must be expended in some way or other in case the rotor bursts.

An example taken from actual experience will serve to illustrate the amount of energy that is liberated even by the rupture of a rotor of small size. In the case we have in mind the disk, shaft flanges, bolts, and blades had an aggregate weight of about 300 pounds, and the normal speed of the disk was 10,820 revolutions per minute. While the machine was in operation a piece of the rotor, weighing about 60 pounds, broke off and was hurled through the casing. The linear speed of the centre of gravity of this piece was 656 feet per second, so that the amount of energy liberated when this piece broke away was approximately equal to that generated by a 730-horsepower engine in one second. It is easily imagined what serious damage such an amount of energy could do when once set free, and correspondingly easy to understand that in the case of the rupture of a rotor of large size the consequences might be almost incalculable. In this particular case two men were killed and two others were severely injured, and the property loss was also heavy.

In another accident the rotor of a small impulse turbine having a normal speed of 9,000 revolutions per minute, burst through the casing, broke off a 6-inch exhaust pipe, leaped over a small air compressor to the floor, and started to roll up a flight of cement stairs leading out of the engine room. Still whirling rapidly, it stopped at the third step, into which it ground a depression about five inches. It then turned back into the engine room and ran across the floor for a distance of 35 feet where it struck a foundation wall, after which it veered and crashed into another similar foundation ten feet away, and finally sped across the floor nearly to the starting point.

We might describe other turbine accidents in which both large and small machines figured, but the foregoing accounts are sufficient to emphasize the possibilities of danger, in case of defective material or parts, or if the operators or attendants fail in their duties in any respect. Serious disasters are becoming less frequent, however, and we believe that well-designed, modern turbines, when operated carefully and intelligently, present no greater hazard than reciprocating engines.

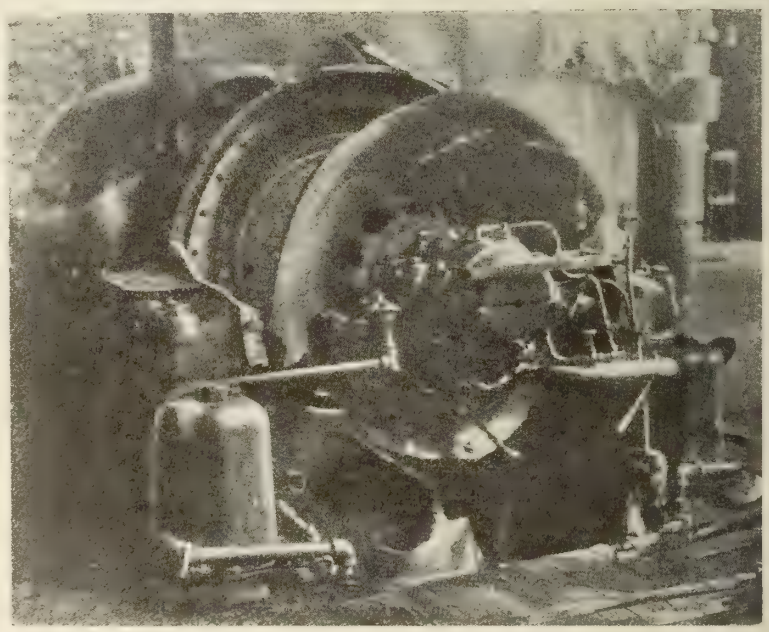

FIG. 1. ILLUSTRATING WRECK OF A SMALL TURBINE

Serious damage to steam turbines may arise from quite a number of causes, but the commonest immediate sources of trouble are: (1) rubbing between the revolving and stationary members, and (2) over-speed. As stated elsewhere in this article, the turbine should be shut down as soon as the first sign of rubbing is perceived, and the difficulty should be remedied before the machine is again put in operation. In case of over-speed it is also imperative to shut down the turbine immediately, and if trouble of this kind occurs the turbine mechanism ought to be capable of controlling the steam supply immediately, automatically and effectively.

Every turbine should have one main governing mechanism, competent to keep the machine running at designed speed under all conditions of load, and it should also have an emergency governor or control, which will promptly shut down the turbine whenever the regular governing device does not function. To safeguard both of these mechanisms it is necessary to have the governing apparatus in proper working order, and it should be maintained in this condition by frequent examinations and tests. It is equally important to ascertain, at short intervals, if the emergency control, and all the mechanism connected with it, is in good operating condition. Special attention in this respect should be given after either the controlling-valve stems or the throttle-valve have been repacked. Accidents have been known to occur on account of using packing containing a considerable amount of rubber, which would swell and render the mechanism inoperative as soon as the packing boxes became heated.

Failure of the regular governing apparatus may result from ordinary wear, or it may be brought about in other ways. If the load is suddenly thrown off the governor is supposed to cut off the steam supply promptly and prevent racing. Not infrequently, however, the governor valve becomes worn so that it admits a considerable quantity of steam, even when it is supposed to be closed; and if the turbine is doing little or no work it may speed up to the bursting-point in consequence. To guard against an accident of this kind the valve should be kept in first-class condition at all times. Attendants in charge of a steam turbine sometimes change the setting of the governor, and they occasionally take it upon themselves to disconnect the governor entirely for a time, in case it does not work satisfactorily. This practice is too evidently dangerous to require discussion. Even when the governor is not disconnected, the men in charge sometimes undertake to run the turbine at a higher speed than that for which it was designed. This should never be done, because an increase in speed corresponds to a decrease in the factor of safety under which the machine is operated, and is likely to lead to disastrous results. It is important to remember that the stress to which the rotating parts are subjected increases in proportion to the square of the speed, so that doubling the speed increases the stresses fourfold. The attendant will frequently re-adjust the governor so that its valve is allowed more travel than the governor can take care of. We do not need to point out the danger that an error of this kind involves.

To provide for emergencies and prevent racing in case of the failure of the main governing apparatus, upon which dependence is placed for the regulation of the speed, every steam turbine should be provided, as we have said, with a separate and wholly independent safety stop, in no way connected with the main governing mechanism. The safety stop should not merely reduce the steam supply, as the ordinary governor does, but should cut it off completely and quickly as soon as the speed reaches a certain definite limit. This limit may perhaps be ten per cent. in excess of the ordinary running speed, but the builder of the machine should be consulted on this point, and his counsel should be followed. It is specially important to see that the emergency stop is maintained in good condition at all times, because when a turbine starts to race there is usually a very small margin of time for action, if an accident is to be averted. The closing of a throttle-valve of the ordinary type requires more time than is safely available, after the turbine has begun to speed up toward a dangerous limit. The valve that is operated by the emergency stop should be of the quick-acting type, so that the steam will be shut off without a single second of needless delay. To test the emergency stop and insure that it is constantly in good working order, it is advisable to trip it every time the machine is shut down, instead of using the throttle-valve for this purpose, in the usual way. It is important to protect the emergency stop and all its connections in such a way that the stop cannot be rendered inoperative by accidents external to the turbine itself. For example, the turbine may be operating an electric generator, and the generator may burst and some of the fragments may wreck or incapacitate the governing apparatus and the emergency control connected with the turbine. In a case of this kind the load would be suddenly thrown off the turbine, and the most serious consequences would result. It is always possible to imagine unlikely things that would lead to accidents, but that is no good and sufficient reason why the emergency stop on a turbine or a reciprocating engine should not be reasonably protected against damage from external causes.

Many turbines have valves in the exhaust lines, or discharge their steam into main headers having no valves in them. The attendant sometimes forgets to open these valves, and when this occurs a dangerous condition is at once created, unless special provision is made for such a contingency. Every turbine that is installed in such a way that the exhaust line can be closed must be provided with a relief valve of sufficient capacity to discharge all the steam that can enter through the nozzles or other steam openings, without permitting the pressure inside the casing to rise higher than the limit that has been selected in advance as the limit of safety. In small machines the relief valve is commonly placed in the casing, so that it forms a part of the turbine itself; but in larger ones the relief valves are often installed separately, and connected with the casings by fittings or pipes of suitable size The relief valve should be installed so that it cannot be shut off from the turbine by means of a stop-valve. For example, when the turbine is run condensing and there is a stop-valve between the turbine and the condenser, the relief valve should be connected on the side of the stop valve that is next to the turbine. This point is sometimes overlooked by designers and erectors, and yet it is exceedingly important because serious accidents are likely to occur if it is neglected. A relief valve that is placed on the condenser side of the stop valve will operate properly if the stop-valve is open; but it is a mistake to install any safety device in such a way as to make its effectiveness depend needlessly upon the thoughtfulness of the attendant.

If the governor valve of a small turbine is operated directly by the governor without a relay, it is very important that the valve should rest on its seat before the governor has reached the limit of its travel. Unless this adjustment is properly made and maintained, there is danger of over-speeding to the bursting point. Turbine attendants are sometimes advised, therefore, to test this point by taking off the governor spring when the turbine is shut down, pulling out on the weights until the valve rests securely on its seat and then noting whether or not the governor is still within its limit of travel. This practice is itself dangerous, however, unless the examination is made by a specially trained expert, because it is hard to put the governor back in its original position and give the weights the proper attention. The governor should never be dismantled and taken apart by the attendant unless it is absolutely necessary to do so. Any desired verification of the kind suggested above should be made by somebody assigned by, or approved by, the builder of the machine.

Many other items connected with the operation of small turbines require careful attention, if hazardous conditions are to be avoided. Adjustment of the setting of the governor valve should never be attempted except when absolutely necessary, and then only by an experienced man who should make sure that the adjustment will not prevent the

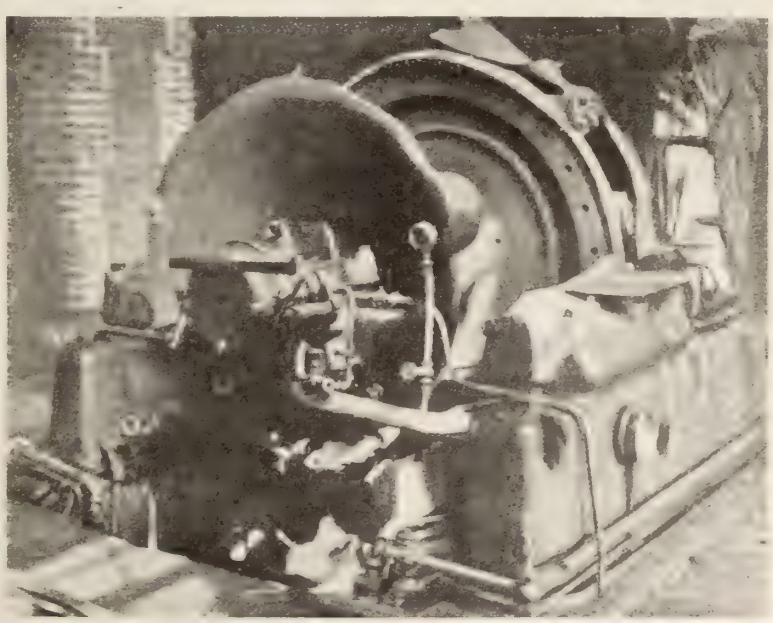

FIG. 2. ANOTHER VIEW OF THE TURBINE SHOWN IN FIG. 1

governor from closing the valve. The packing of the governor-valve stem should be attended to only when the turbine is shut down, and should be tested for sticking before the machine is put in service, and again (as indicated above) after the packing has become heated up. Governor valves are likely to become leaky in time, and hence they should be carefully watched. The governor-valve stems are usually made small in diameter to prevent leakage, and they may become bent quite easily from knocks or shocks, so that the governor will not operate properly.

Under ordinary circumstances the emergency valves of small turbines are seldom required to operate. There is therefore the likelihood that the automatic device, on account of long disuse, will fail to operate when an emergency arises. To guard against such a contingency these devices should be tested frequently, and any failure to function properly should be investigated and the trouble remedied before the turbine is restored to service. When an overspeed device operates without apparent cause, the reason should be sought, and located and remedied before the turbine is started again, even though an interruption in service is entailed thereby. These points, as well as others, are usually embodied in the instructions provided by the builders, and every man in the plant who is concerned in the care and operation of the turbine should have a copy of the instructions and become familiar with them. To emphasize the importance of this knowledge we may mention the fact that there are marked differences in the methods of lining-up and setting-up turbines of the various makes and types. For example, the same method cannot be employed for installing and lining up a rigid-frame turbine and one which has four bearings and is provided with a flexible coupling. There are also other more or less important dissimilarities in installation and operation. In our opinion each man should make just as serious a study of the particular turbine that he is to operate as he would of the various matters with which he must become familiar in order to obtain his license as stationary engineer.

Another prominent cause of trouble in connection with steam turbines is lack of balance of the rotating parts. This may arise in various ways. The rotor is supposed to be carefully balanced by the manufacturer of the turbine, but the balance may be disturbed by the making of repairs and in various other ways. Blades breaking off from the rotor will produce lack of balance to an extent corresponding to the number of blades that are lost, and masses of water entering the turbine from any cause may produce a very considerable lack of balance momentarily, or may give the shaft a fixed set, resulting in permanent unbalance.

The foundation for the turbine (especially if the machine is of large size) should be laid with extreme care, in order to insure absolute solidity. At certain speeds, called "critical speeds," vibration is specially likely to occur, even when none is noticeable above or below these critical speeds. In accelerating a turbine the critical speed should be passed as quickly as possible, especially if a flexible shaft is used, but except as this speed is approached the turbine should be accelerated slowly because otherwise the rotor is likely to become distorted and cause the blades to come in contact with the casing, and break. Whenever possible, the load should also be applied gradually after the turbine has been brought up to speed. Unless care is taken in these respects, troublesome vibrations may develop and persist for a long time. The present practice of nearly all steam-turbine makers, however, is to design their rotors so that the operating speeds are well below their critical speeds, and when it is known that this point has received attention by the builder, the turbine can be accelerated slowly throughout the entire range with entire safety.

Vibration is not always caused by lack of balance in the turbine itself. It may also be due to defective balancing in the electrical part of the unit, or to poor alignment of the shafting. Correct alignment is of extreme importance. Flexible couplings are sometimes employed to prevent trouble due to misalignment, but, contrary to general opinion, they do not entirely obviate it, and particularly when they are used with small high-speed turbines. Some small auxiliary turbines must be set a trifle low, because otherwise the expansion caused by the high temperature during operation with throw them out of line. Points of this kind are fully covered in the instructions furnished by the manufacturers, and these instructions should be followed absolutely.

Mis-alignment may also be caused by improper piping installations in which the piping is arranged in such a manner that an excessive load is imposed on the turbine and forces it out of line.

A large turbine should be started noncondensing, or with a low vacuum (not over 15 inches) in order that the large section of the rotor at the exhaust end may be properly warmed. At the outset a little steam should be admitted to blow out the drain water, then the throttle should be opened up further for a moment, until the rotor starts turning. The throttle should then be tightly closed and almost immediately opened again—juts enough to keep the rotor moving slowly. In this way the steam reaches all parts of the turbine, and the heating of the various sections or stages is approximately uniform, whereas, if steam is admitted in small quantities while the rotor is stationary some portions become hotter than the other portions, and this causes distortion and strain, and lays the foundation for excessive vibration later on.

In heating up a turbine the drain pipes should be left open until full speed is attained. Small turbines may require little or no preliminary warming up, and the tendency of builders is constantly in the direction of reducing the warming up period of the larger machines also, but the man in charge should never undertake to reduce the time on his own responsibility only, because he may do the turbine great harm in this way. It should be understood that these remarks about heating up are general. The builders of turbines give special directions for the warming up of each type and size of machine, and these directions must be faithfully followed in every particular.

A turbine running on a light load with the rotating parts rubbing against the stationary parts generates heat faster than steam flow can carry it away. This will cause distortion of the parts affected, and if continued for some time will seriously damage or even wreck the machine. Whenever rubbing is noticed, immediate steps should be taken to remedy it by finding the cause and removing it. Rubbing must never be permitted to go on under any circumstances.

A turbine that is out of service for some time, or that is used intermittently, is subject to corrosion from throttle leakage. It is hardly possible to emphasize the importance of this danger too strongly as it is specially harmful to a turbine to have small quantities of steam and water going through it when it is standing still, and the machine will deteriorate rapidly under such conditions.

The junctions of the blades with the disk are specially susceptible. When steam leaks in through the throttle of a large turbine it is also likely to cause distortion of the spindle on account of the uneven expansion that occurs when the steam blows in on one side. The use of brass lining strips helps to reduce corrosion from the throttle leakage, but the only right thing to do is to see that no leakage occurs. The throttle should receive careful attention, and should be kept in first class condition at all times. In the steam line of every large turbine there should be two valves with a good sized "leak-off" between them. By adopting an arrangement of this kind and closing both valves whenever the turbine is shut down, it is an easy matter to prevent damage from leakage.

Water is always likely to make serious trouble in a turbine, from whatever source it comes. (This is the case also with reciprocating engines.) It is likely to back up from the condenser unless special provision is made to prevent action of this kind. The impact due to a mass of water striking against the blades of a turbine may be very considerable if the machine is running at full speed, and it is quite likely to strip the blades or lead to vibration and other serious results. This source of trouble is pretty generally recognized, and turbines are usually guarded satisfactorily against flooding from the condenser.

Water is sometimes carried from the boilers over into the turbine through the steam supply line, and when this occurs the water is likely to do serious damage. The danger is specially great when the water comes in large quantities, as is likely to happen if the steam pipes contain pockets or loops, or are otherwise faulty in design. It is therefore advisable to install a separator of adequate

size in the steam main, just before it reaches the turbine, and special care should be taken to operate the boilers at a reasonable duty, and also to keep the steam main and all other parts of the supply system in good order. In these days of high superheating the damage to a turbine from the entrance of water through the steam main is likely to be materially greater than in the old days of saturated steam or slight superheat, because the temperature changes that are produced by the water in the turbine are far more severe, and the distortions of the revolving and stationary elements may be so bad that serious rubbing will take place. (Many engineers are of the opinion that superheated steam can never carry moisture, and hence that there can be no trouble from water in turbines using superheated steam. This is not the case, however.) In well-designed stations this can be overcome, but it is often due to permitting the water level to get too high in the boilers. In many stations automatic devices are employed to guard against this, but, like all other automatic devices, they occasionally go wrong. If a turbine is loaded too suddenly after it has come to speed, the governor will open quickly and admit a correspondingly large quantity of steam to take care of the increase in the work to be done, and when this occurs slugs of water are likely to be carried over by the steam.

Turbine accidents have occurred from leaving tools, fittings, or other objects inside the machine when closing it up after making repairs. In some machines the various parts could not be properly assembled if any sizable object were left inside, but in all of them there will be spaces in which small objects could be left with corresponding promise of trouble, and the possibility of this should be borne in mind whenever turbines are opened up for repairs or inspection.

It is extremely important in the operation of a turbine to apply constant lubrication to the bearings and to use oil of the best quality. An alarm or some other device might be used to advantage to give notice in case the supply in the oiling system falls below the point of safety. If a bearing becomes unduly heated the engineer in charge should immediately increase the supply of oil, and if this is not followed by marked improvement the turbine should be stopped and the cause of the trouble investigated. The oil wells should be cleaned out before starting the turbine, and care should be taken to see that they are kept clean. If sediment accumulates in the oil wells it is also likely to collect in the oil grooves where it may carbonize and eventually entirely fill the grooves.

It is of great importance to test carefully each and every part which runs at high speed during the operation of the turbine. The preliminary inspection of a new rotor should not consist merely of a careful examination, but a test run should also be included in the specifications. The test run should be continued for some time after the machine has become thoroughly warmed up, and the speed should be varied from ten to fifteen per cent. above the normal speed of operation. The importance of a test run of this kind, when a new machine or a new rotor is installed, cannot be emphasized too strongly.

When a turbine is opened up for inspection or repairs, the work should be supervised by a skilled man sent by the manufacturer of the turbine, until the operating engineer has become thoroughly familiar with it, and when the machine is large or complicated, the manufacturer should always be consulted before it is opened up. In removing and handling the rotor, special care should be taken to avoid injury to the blades and other delicate parts. At the time of such inspection the oiling system should be completely cleaned out and filled with new oil. After the parts have been assembled again, and before admitting steam to the machine, the rotor should be turned over by hand to see that it does not bind nor meet with serious resistance to rotataion. Inspections of the kind indicated should be made at least once a year, and every part of the turbine should be examined at such times, for defects of every kind.

In marine practice it is customary to make readings every four hours, for verifying the correctness of the position of the rotor so far as "fore-and-aft" displacements are concerned. Any error or departure from the standard position is then corrected by adjusting the nuts on the thrust bearing. Similar precautions should be taken on stationary turbines, if possible, when they are run under conditions analogous to those prevailing aboard ship—that is, when they are run with an end-thrust on the shaft, as in operating pumps of certain forms and other special machinery.

No person should undertake to operate a steam turbine until he has received thorough instruction with regard to the machine and the way it is to be used. All builders of turbines should furnish complete and detailed information on all essential points. This should be done not only by issuing printed circulars and booklets, but also, when the turbine is first installed, by supplying experienced men to give the necessary instruction, at first hand, directly to the employees who are to be responsible for the machine. These experts should remain at the plant until it is certain that the attendants are fully qualified to take charge.

The theoretical considerations involved in the operation of the turbine form a highly specialized branch of engineering, and a considerable amount of study of the subject is essential before innovations of any kind can be tried with prospects of success. For example, a turbine designed to run non-condensing should not be operated condensing except after consultation with some one qualified to express an intelligent opinion as to the practicability of the change, and a turbine designed for a constant pressure should not be used on what is called the "mixed pressure" system, unless similar care has been taken to ascertain that such change is advisable as well as satisfactory, and that suitable steps are taken to prevent a runaway. In general, the attendant should never undertake anything out of the ordinary with the machine, until he has taken counsel with somebody who has had considerable experience in such matters. Under all circumstances, he should be content to operate the turbine under regular routine conditions, which have been proved by experience to be safe.

ANCHOR ICE UPSETS CHICAGO'S WATER SUPPLY

On January 12 the water supply in the north and northwest districts of Chicago was almost completely paralyzed and a consequent suspension of industry was caused and domestic inconvenience took place. Anchor ice clogged the intakes to the water supply channels. Under tremendous handicap and danger, workmen resorted to the use of dynamite to force a pathway through the ice to affected points. The ice had blocked the water valves, cutting off almost completely the flow of water to the pumping stations. The Lakeview pumping station, with a daily capacity of 100,000,000 gallans, was crippled because three of its boilers were put out of commission.

"WHAT MAKES THE ENGINE GO"

Dear sirs, about the engine, well,
We write to let you know
We've waded through the booklet on
"What makes the engine go."
It took us close on half a day
To read through all the guff;
The engine goes alright, but don't
Keep goin' long enough.
It's very good to understand
What makes the engine go,
But why the deuce the ——— thing stops
Is what we want to know.
So now we're making this request,
While tears and curses drop:
Please send along a booklet on
What makes the engine stop.
The folks around here all await
With interest, your reply
To them the reasons why she goes
Don't seem to signify.
So while we wait and chew the cud
Don't let the matter flop;
For ———sake write and let us know
What makes the blighter stop.

—From a "Cocky" Customer.
(Censored.)

According to "Elektrotechnic und Maschinebau," special apparatus has recently been contrived to measure rapidly fluctuating temperatures such as an ordinary thermometer is too sluggish to record. At the point of measurement, wires of platino-iridium, 0.02 mm. diameter, are inserted and are connected to a galvanometer. The deflection varies with the resistance of the wires, and it is stated that variations in temperature with a frequency of ten per second may be noted. It is anticipated that the apparatus will be specially useful for studying cyclical variations in temperature in the cylinders of steam engines and combustion engines.

Electrical Energy Generating Stations---I

The Second of Several Articles Dealing With the Design of Power Plants, Both From the Electrical Standpoint and From That of the Prime Mover. Station Layout is Discussed

By TERRELL CROFT

(Copyright; all rights reserved by the author)

The Selection of the Capacities and Ratings of the Generators is a question which is always worthy of careful consideration. As a rule, in modern installations, each generator and its prime mover constitutes a complete unit. It is almost always the best practice to instal two or more such units in every plant so that it will be possible, under all ordinary operating conditions, to work at least one of the units at its most efficient load, hence, in determining capacities and ratings it is always desirable to base the determination upon the graph of the load to be imposed on the station. It is, however, seldom, possible to base the selection solely on the load graph because provision should be made for a certain growth in load.

Also the question of reserve capacity—that is, protection against accident and breakdown—should be considered.

The Rating of the Generator Should be Proportioned to the Characteristics of the Prime Mover. Both steam engine and water-wheel prime movers operate at maximum efficiency at certain definite loads. At loads greater or smaller than this maximum-efficiency load, there will be a material decrease in efficiency. With internal combustion engine prime movers (prime movers of this type have no overload capacity) the point of greatest efficiency is the maximum load which the prime mover will pull. These elements should be given due consideration.

In Providing Reserve Capacity in generating equipment, that is, capacity which may be utilized in case of a breakdown of some of the generating apparatus, there are two expedients which may be adopted. That is, reserve capacity may be provided by (1) installing an extra unit or extra units which may be operated when one of the regular units is inoperative, and (2) the overload capacity of the regular units.

*Note.**—With the method of rating engine-driven units which is generally used, which provides a liberal overload capacity for a few hours, the second expedient works out satisfactorily. For example, a plant of five units, each of which has an overload capacity of 25 per cent., can have one unit taken out of service when all of the units are operating at full load without placing an excessive load on the remaining units. It is now the almost standard practice of practically all steam-turbine manufacturers to rate their units on a maximum basis, that is, without any overload capacity. Under this method of rating it is necessary to utilize the first expedient noted above to provide reserve for emergencies. To maintain the reserve capacity at a minimum it may be desirable to have at least five or six units in the plant. With five units to carry the load and one reserve unit, there is, then, only 17 per cent. of the installation held in reserve. If one reserve unit is considered inadequate, the addition of another increases the reserve capacity to about 29 per cent. of the total.

*J. W. Shuster, "Tendencies in Central Station Practice," "Electrical Review," Mar. 3rd, 1917.

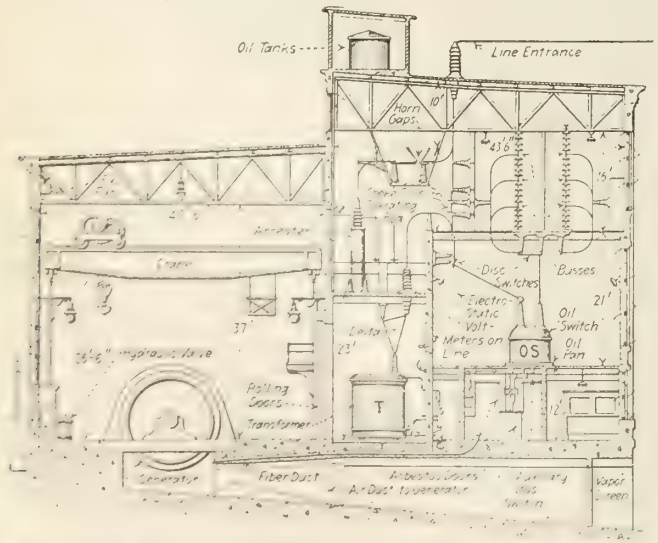

FIG. 8—SECTIONAL ELEVATION OF A TYPICAL 110,000 VOLT HYDRO-ELECTRIC GENERATING STATION.

Water-wheel and internal-combustion engine driven units have no overload capacity, hence in stations driven by prime movers of this type, reserve capacity must be provided as outlined in expedient (2) above. That is, additional units must be provided for reserve.

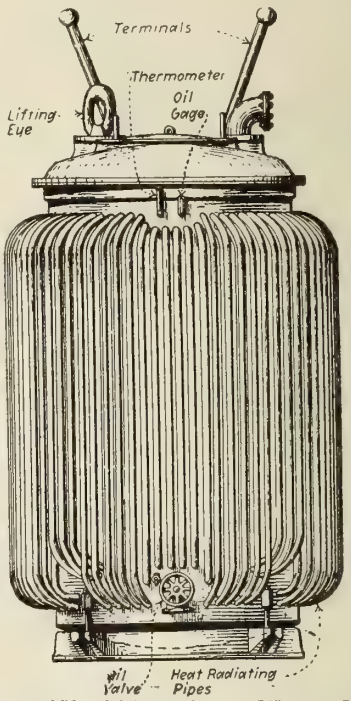

FIG. 9—OIL-COOLED OR SELF-COOLING TRANSFORMER. (This shows the tubular type.)

Low Power-factor Decreases the Effective Capacity of a Generator so that if a station is to operate at a power-factor other than 100 per cent. this should be recognized.

Example. If the power factor of a plant is 100 per cent. then for a 100 kva. generator, in such a plant, a prime mover capable of developing approximately 100 kw. output should be provided for the generator. However, if the power factor of the load which the plant serves is only 75 per cent. then to drive a 100-kva. generator a prime mover of only approximately 75 kw. output is necessary. If a 100-kw. prime mover were used approximately 25 per cent or one-fourth of its capacity would be unavailable. Furthermore the prime mover, instead of being fully loaded, that is, operating at high efficiency when the generator was fully loaded, would be operating at only three-fourths load with correspondingly low efficiency. (In the preceding example a generator efficiency of 100 per cent has been assumed.) Actually the efficiency of a generator is always less than 100 per cent., but the principle involved is evident from the above, even if the generator efficiency is not considered.

The Unit Principle should be Utilized wherever possible.

That is, all of the units in the plant should, insofar as feasible, be duplicates. The different essential elements of the installation, such as generating elements (comprising generator prime mover and its auxiliary apparatus) transformers, boilers, etc., should be arranged in groups or composite units. Each one of these groups should in essence be a complete central

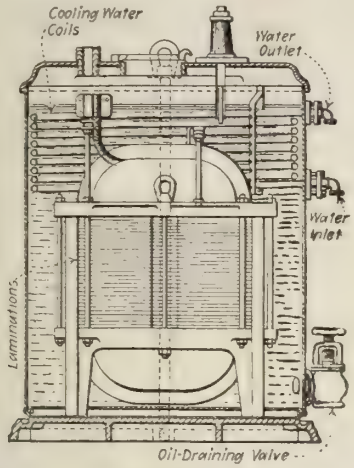

FIG. 10—THE WATER COOLED TRANSFORMER.

station installation in itself. Then, if this plan is followed, a breakdown in some component piece of apparatus should affect only the group of which that component forms a part. The other groups should be capable of uninterrupted operation.

The Factors Which Should Determine the Location of the Apparatus in a generating station are: (1) simplicity, (2) reliability of operation, and (3) extensions. Upon study, it will be evident that, in general, the unit system of arrangement described in the preceding Art. satisfies all of these requirements more completely than would any other arrangement.

In Locating the Prime Movers and Generators they should ordinarily be arranged on the main floor of the station. There should always be at least sufficient distance between units to admit a free passage around them and so that repairs can be effected without any unnecessary waste of time. In steam plants the condensers are usually located in the basement and the principal piping (Fig. 6) carried below the main floor.

The Exciters* should have a capacity sufficient for all of the synchronous apparatus in the station when all of the synchronous machines are operating at their maximum loads and at the operating power factor. It is not sufficient to provide only enough exciter capacity for excitation for the machines when they are running at unity power factor, The excitation required for power factors lower than unity is considerably higher than that required at unity.

The System of Excitation which is now considered good practice and which affords maximum reliability is that in which all of the exciting current is obtained from a common source. This common source should comprise as few units as possible. One or two units are generally provided for normal excitation

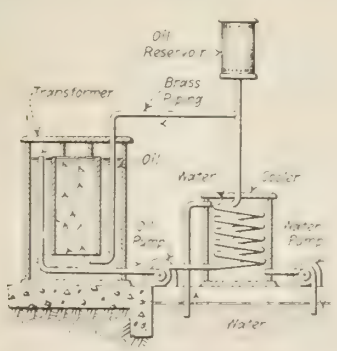

FIG. 12—THE CIRCULATING OIL-TYPE TRANSFORMER.

and a third is installed as reserve. It is always good practice to have the regular exciter driven by prime movers such as steam engines or water-wheels, while the reserve unit is motor-driven.

Note. Another system of excitation which is now being used frequently is to instal (for driving the exciters) low-voltage generators each of which is driven by a non-condensing steam turbine or a water-wheel. The exciters are then motor-driven, energy therefore being obtained from the low-voltage generator. The steam from the turbines exhausts into the feed water heaters. In addition to the exciters all of the other auxiliaries, such as circulating pumps, etc., are motor driven.

The Exciter Voltage is for small and medium sized plants 125 volts. For large installation 250-volt excitation is more economical.

In Locating the Exciters in a station it is, in general, desirable to place them near the centre of the generator room so that the excitation wiring will involve minimum cost.

Note. Where one exciter is furnished for each generator, it should be located as close as is feasible to its generator. Exciters direct-connected to their generators are often used.

Automatic Voltage Regulators are always installed in modern stations. These, by acting on the fields of the exciters, maintain the alternating-current voltage constant at the bus bars regardless of changes (within reasonable limits) of load on station or of changes in prime mover speed. Voltage regulators are usually located on or near the switchboard.

Transformers

The Number and the Capacities of the Transformers should be determined by the characteristics of the station and the load which it serves. In stations transmitting at medium or low

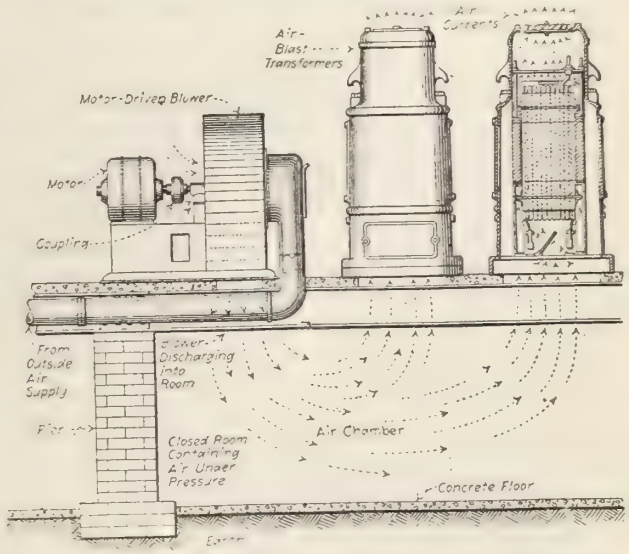

FIG. 11—AN AIR-BLAST TRANSFORMER INSTALLATION.

voltage it is usually considered best practice to instal one bank of transformers for each generating unit, following out the unit principle recommended above. However, where the transmission voltage is high, the transformer bank should form a unit with the transmission line, each of the transmission lines terminating in the station in one of these units. Where this arrangement is followed, switching on the high-tension side of the transformers is unnecessary, as all of the switching can then be effected on the low-tension side of the transformers. In locating the transformers in the station, they are usually placed (Figs. 6 and 8) on the main floor back of the generators. They are enclosed in suitable fire-proof compartments. A track is installed along in front of the tier of compartments so that the transformer may, when necessary, be readily removed for repairs.

Either Single-Phase or Three-Phase Transformers can be used. The modern tendency appears to be toward the utilization of three-phase transformers where the application of such is feasible.

Note. The conditions under which single-phase transformers are preferable are where only one group is installed or where the expense of a spare transformer is unwarranted. In such installations the burning out of one phase of a three-

phase unit involves considerable inconvenience, since the transformer would have to be disconnected before repairs could be made. If single-phase transformers are used and connected in delta (on both primary and secondary) the damaged unit can be readily cut out and the other two operated at normal temperature—58 per cent. of the rated

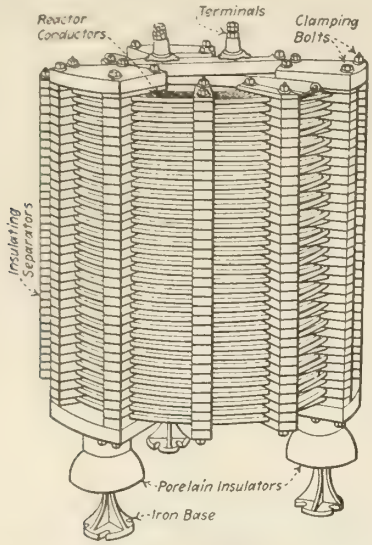

FIG. 13—A CURRENT LIMITING REACTOR.

normal capacity of the group—until the damaged unit can be replaced.

Note. With the three-phase, shell-type transformers both the primary and secondary windings are delta connected. Trouble in one phase will not prevent the use of the other two in open delta by short-circuiting both the primary and secondary of the damaged phase and cutting it out of the circuit. The magnetic flux in that section is entirely neutralized. Three-phase transformers may be used in moderate voltage installations having a large number of units. For high-voltage developments where each transformer bank should be of a capacity equal to that of the line, which it serves it is usually necessary to select single-phase transformers so as to obtain the required capacity and minimize the cost of the spare unit.

Transformers May be Either of the Oil-Cooled, Water-Cooled or the Air-Blast Type. In the oil-cooled (Fig. 9) or self-cooled type the oil, heated by contact with the transformer core and winding, rises to the top in the transformer case, from which the heat is radiated into the air. The tanks of self-cooling transformers are, therefore, usually made of corrugated sheet steel to provide maximum radiating surface. The self-cooled transformers are the most frequently used. Where water for cooling purposes is available, the water-cooled

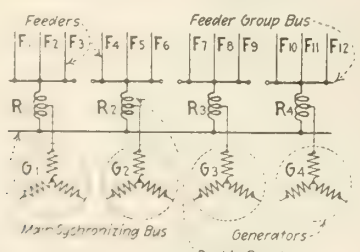

FIG. 14—SINGLE LINE DIAGRAM OF COMBINED GENERATOR, BUS AND FEEDER FROUP REACTANCE COIL.

transformer (Fig. 10) is the most economical in first cost. In a transformer of this type, the oil circulates in a manner similar to that in a self-cooled unit. However, the greater proportion of the heat is carried away by the water forced through a pipe coil which is submerged in the hottest oil in the top of the transformer. Ordinarily the water rate is approximately one-half gallon per minute per kw. loss, the temperature of the incoming water being 59 deg. Fahr. In the air-blast transformer (Fig. 11), the cooling is effected by forcing a blast of air through ducts or spaces provided in the transformer structure. Transformers of this type are applicable for voltages

*I. E. E., "Standardization Rules."

up to about 33,000 but they are being rapidly superseded by those of the self-cooling type.

Note. Circulating-oil-type transformers (Fig. 12) may be adopted where the only water available for cooling is hard or contains sediment. Such sediment might deposit on the insides of the coils of water-cooled transformer. But with the arrangement shown in the illustration, the deposit would be on the outside of the oil coils, hence read ly removed.

External Reactances or Reactors* (Fig. 13) are now used in many stations of large capacity to limit the excessive current which would flow, if these reactors were not inserted, in the case of a short-circuit on the system. It is not feasible to incorporate sufficient reactance in high-voltage turbo-generators,

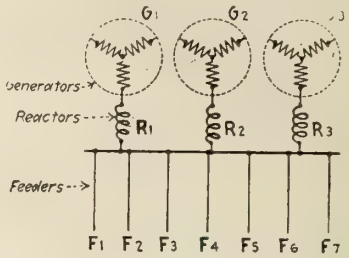

FIG. 15—SINGLE LINE DIAGRAM SHOWING REACTORS INSTALLED ON FEEDER GROUPS.

hence, with generators of large capacity of this type, current-limiting reactances may be inserted in the generator lead or between the bus sections (Figs. 14, 15 and 16) or in the outgoing feeders.

The Percentage Reactance of a Reactor** is the ratio (expressed in per cent.) of the voltage drop across it, when full-load current flows to the voltage of the system.

Example. If the full-load current is 100 amp. (on a 10,000-volt, single-phase system or on a three-phase system with 10,000 volts to neutral) the drop across a coil having a reactance of 5 ohms will be : $100 \times 5 = 500$ volts. The percentage reactance of the coil will be $100 \times 500 \div 10{,}000 = 5$ per cent. Or, if the full load current is 100 amp. on a three-phase system, with 10,000 volts between phases, then the percentage reactance of the coil having a reactance of 5 ohms will be: $100 \times 500 \div (10{,}000 \times 0.577) = 8.66$ per cent.

The short-circuit current which will flow is: 100 ÷ (the percentage reactance of the coil + the percentage reactance of the generator) × (full load current.) In the above case, if the generator reactance is also 5 per cent., the short-circuit current will be 10 × full-load current. On short circuit, the reactance will, in this case, have one-half the no-load voltage impressed across it.

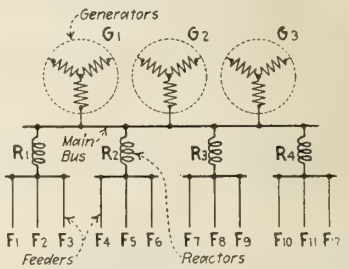

FIG. 16—REACTORS INSERTED IN GENERATOR LEADS.

The Location of the Switchboard and Switchgear should be determined by the capacity, voltage and general arrangement of the plant. In low-voltage, small-capacity plants where self-contained switchboards are used, all of the switchgear is mounted directly on or adjacent to the switchboard. The switchboard is installed in a convenient central location near one of the walls on the main floor of the station. Where the switchboard is of the remote-control type there are many different arrangements which may be used. It is usually considered desirable to so locate the control board that an unobstructed view of the station may be had from it. However, in certain very large installations, the control board is in a room entirely separate from the generating room. The bus bars and oil switches are located on the various floors of the switch house.* See Figs. 6 and 8.

THE METERING OF STEAM DESIRABLE IN POWER PLANT OPERATION

It is only within a comparatively few years that engineers have interested themselves in the metering of steam, but the attention now devoted to the efficiency of operation of industrial plants has created a demand for apparatus which will provide definite information as to the quantity of steam flowing through a pipe.

The question of steam measurement first came into prominence in connection with tests of steam engine efficiency, and the general practice was to condense the steam and to measure or weigh the resulting water. The measurement of steam—as steam— is a different matter altogether, and a far more difficult one.

Field for Steam Measurement

The most obvious field for steam measurement is when steam is sold to an outside purchaser or supplied to some department of a factory which has to keep separate costs. The power plant, as the producers, are not concerned with the efficiency with which such steam may be used, but have to be paid for what they supply. On the other hand, the consumers of steam may rightly demand that they should be charged for steam only and not for water of condensation entrained with the steam which might otherwise be debited to them. Again, in these days of large boiler plants, the engineer in charge should know how much steam each boiler, or at least each battery of boilers, produces in order to have a check upon their evaporative efficiency as affected by the kind of coal burnt, the method of firing, or the condition of the boilers. Individual water-meters on the feed lines of each boiler, even when fitted, as they very rarely are, do not adequately meet the case, for they register all water entering the boilers, including much that is not turned into steam at all but expended in blowing down, etc. Moreover, the ordinary water-meter merely counts the number of pounds or gallons which have passed and gives no indication of the rate of flow at any time. Hence there is an increasing tendency for the provision of steam flow meters in boiler houses where a high efficiency of operation is aimed at.

Numerous other cases in which the direct measurement of steam is desirable or necessary will at once occur to the mind. The steam supplied to gas producers, for example, must be measured as steam or not at all, and a large number of industrial or chemical processes use steam, the amount of which must be known by the management if the best results are to be obtained either from the process or from the steam generating plant.

Principles

Most practical steam meters are based upon one or other of two principles. Either there is a slight constriction inserted on the steam pipe so as to cause a small pressure difference on the two sides, which will vary with the amount of steam passing, or the velocity of the flowing steam is measured by a sort of Pitot tube. The actual measuring instrument can be placed at any convenient distance from the steam pipe and is connected to it by means of two small copper tubes filled with water of condensation, which transmit the differential pressure to the instrument. The latter may be constructed either simply to indicate on a dial or scale the rate of flow of the steam at any instant, or to record the rate of flow graphically on a diagram, or to integrate numerically by means of a counting mechanism the quantity which has passed in any given time. Indeed all these functions can be combined in one instrument if desired.

When the principle of the constricted pipe is employed the quantity of steam passing per unit time is taken as being directly proportional to the square root of the difference of pressure on the two sides of the constriction. This statement, however, is strictly true, only if the pressure and the superheat of the steam are constant.

The principle of the Pitot tube has found favor with perhaps the majority of inventors. In its simplest form the apparatus for determining the rate of flow comprises two tubes inserted through the side of the steam pipe, one being cut off flush with the inner wall of the pipe and the other bent so that its open end faces the flowing steam. Both tubes are equally submitted to the static pressure of the steam, but the bent one measures also the dynamic pressure due to the velocity. The difference in pressure in the two tubes is therefore a measure of the rate of flow and may be employed to operate an appropriate instrument. Several variants of this arrangement have been adopted, usually with the idea of taking into account the fact that the rate of flow is not uniform over the section of the pipe, being fastest at the centre, and slower nearer the walls. The disturbance of the flow due to the presence of the Pitot tube itself is also a factor to be reckoned with.

An alternative to the principle of the fixed orifice across which the drop of pressure is measured, consists of a variable orifice designed to create a constant pressure drop. The steam is arranged to pass upwards through the seat of an automatically lifting valve, which is therefore held in a higher or lower position according to the rate of flow. A suitable lever mechanism connects the valve with the pointer of the instrument.

Each of these methods has its advantages and its defects. A defect of the Pitot tube principle is that no convenient adjustment can be made to render the instrument suitable for the measurement of rate of flow very much less than the maximum. The reading of the instrument will be proportional to the square of the velocity of the steam in the pipe, and for low velocities the forces acting are so small that the readings are unreliable. The corresponding difficulty, in the case of the instruments depending upon the pressure-drop across an orifice, can be overcome either by inserting a smaller orifice, for which a simple provision is usually made, or by the following method. The constriction causing the pressure drop which has to be measured, consists not of a fixed orifice, but of a kind of butterfly valve which may be locked in either of several positions, according to the rate of flow. The valve is accurately made and carefully calibrated. Thus the instrument is provided with a very simple and effective means of altering its range without the necessity of interfering with the steam pipe in any way. In every type of instrument referred to, however, there is the difficulty of accurate metering when the density of the steam varies, and in all but the best instruments no provision is made for dealing with this condition.

Degree of Accuracy

Although the average steam meter at the present time can hardly be classed with instruments of the highest precision, it must be remembered that measurements of steam in ordinary industrial practice need be no finer than is possible in the case of coal or water. If, what is called "commercial accuracy" can be obtained in the metering of steam, it is as much as the ordinary engineer will demand. Given fairly steady conditions of pressure and superheat, and not too great a variation in the rate of flow, several types of meter will record the quantity of steam passing with an error of about 2 per cent., which is sufficiently accurate for most practical purposes. In the steam meters of foreign design which are now on the market, little attempt seems to have been made to compensate for the errors which must occur if there is any considerable variation in the pressure of the steam. Messrs. George Kent, however, the principal British makers, employ an ingenious automatic correction for this error, and their meters are, in consequence, highly accurate over a considerable range of pressure. The same firm issue with their meters a table by which the readings may be corrected for the density error arising from variations in superheat, but no automatic correction for this error has yet been embodied in commercial instruments. It may be taken that the best steam meters working under commercial conditions will give results correct within plus or minus 2 per cent. at loads ranging from three-quarters to full load. At half load the accuracy will be within 2½ per cent., and from one-quarter load to one-sixth load it will be within 4 per cent. Such accuracy can be obtained only by calibrating each instrument under conditions similar to those under which it will have to work, and this practice is followed by the best makers.

Mechanism of the Instruments

The mechanical methods adopted to

translate the difference of pressure due to the flowing steam, whether determined by a constriction in the pipe or by a Pitot tube, into the actual readings of an instrument differ widely. The simplest instruments of all—namely, those which merely indicate the rate of flow at an instant, sometimes do so by allowing the differential pressure to act upon liquid in one limb of a U-tube, thus causing the liquid to rise in the other limb and to indicate by its height the rate of flow which is read off a suitably graduated scale placed alongside the liquid column. Water is sometimes used as the indicating liquid, partly on account of the ease with which it is automatically supplied by condensation and partly because of the open scale obtained with very small pressures. Mercury, however, is frequently adopted. For equal pressure differences the height of the mercury column is only about one-thirteenth that of a water column, so that it is usual to magnify the motion of the mercury by a float and pulley mechanism, thus giving a large motion of a pointer exactly as in the case of the ordinary type of "weather glass." Another device consists in arranging that the column of mercury as it rises shall successively short-circuit a number of resistances through which a current of constant voltage is flowing. By suitably proportioning the resistances it is possible to arrange that the quantity of current flowing at any time is directly proportioned to the quantity of steam flowing. Thus an ordinary ammeter will serve as an indicating instrument, and a wattmeter similarly can be used for recording the total flow. The use of mercury, however, has certain disadvantages, so that other makers cause the differential pressure to act upon a spring-controlled diaphragm, the movement of which is magnified and transmitted to the pointer by means of a series of levers.

In the Kent steam meters, diaphragms similar to those used in aneroid barometers are employed, and the pressure correction device to which reference has been made above consists of another set of spring-controlled diaphragms subjected to the total steam pressure. The motion of these latter diaphragms is made to alter the leverage with which the differential pressure diaphragms act upon the pointer. The combined action of the two sets of diaphragms therefore causes the pointer to indicate the true quantity of steam which is passing, independently of changes which may take place on its pressure. In addition to recording the rate of flow on a chart these meters may be caused to integrate the quantity of steam which has passed, so that it may be read directly on counting dials. The clockwork mechanism which drives the chart also causes the periodical rotation of a spindle, which is held in gear with the counting mechanism during a part of the revolution, greater or less according to the rate of flow at the time. Other methods of integrating the flow comprise a friction wheel driven by a disc. The disc is rotated uniformly, but the revolutions of the wheel, and therefore of the counting mechanism, depend upon the radial position of the wheel on the disc. This position is controlled by the rate of flow of the steam.—The Engineering Supplement of "The London Times."

FOREWORD OF THE AMERICAN ENGINEERING STANDARDS COMMITTEE

After almost three years of painstaking investigation and discussion by the engineering fraternity, and under the guidance of Professor Comfort A. Adams as chairman, the revised constitution of the American Engineering Standards Committee, along with the by-laws and rules of procedure, has been adopted, and has been ratified by the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Society for Testing Materials, and the three Government departments of Commerce Navy and War. Each of these interests have three representatives, and although the committee as it exists to-day consists of twenty-four members, the new committee is of very wide scope and allows the direct or indirect participation of any one interested in standardization.

The American Engineering Standards Committee makes it possible to give an international status to approved American engineering standards and to co-operate with similar organizations in other countries. Similar organizations are now functioning in Great Britain, France, Switzerland, Holland and Canada.

Through the new committee the methods of arriving at engineering standards will be unified and simplified, and, by co-operation, the duplication of standardization work will be prevented. Standards will not be created without giving all interested an opportunity to participate.

The approval of a standard by the American Engineering Standards Committee does not mean that the committee has itself worked over and approved each detail, but rather that the work has been carried out by a sectional committee adequately representing the industry concerned and sponsored by one or more bodies of ability, experience and standing, so that the result may stand for what is best in American engineering practice.

What the Committee is Doing

The American Engineering Standards Committee is not only ready for business but it has made considerable practical headway. It has approved specifications for standard pipe threads, for which the American Society of Mechanical Engineers and the American Gas Association are sponsors, and are representing America on this subject at an international conference in Paris. Co-operation is in progress with the National Screw Thread Commission authorized by Congress and composed of representatives of the various technical societies, looking forward to standard screw threads. Through this agreement direct co-operative work with the British, which is not possible by the official commission, is being carried out. The committee is also in active co-operation with the Canadians on bridge specifications, with the British on specifications for machine tools, and with the Swiss on specifications for ball bearings. In each case the detailed work is being carried out by sponsor bodies by means of sectional committees.

A large conference, in which practically all national organizations interested in industrial safety, has unanimously voted that all industrial safety codes should be prepared under the auspices of the American Engineering Standards Committee.

Now that the organization of the committee has assumed such definite and precise form, no doubt its activities will be greatly extended and accelerated.

How the Committee Operates

Any organization may request the committee to approve standards which it has formulated or to approve committees that it has appointed, and by so doing becomes a sponsor society. Two or more organizations may act as joint sponsors. Approval of a standard is given when it is the substantially unanimous conclusion of a section committee made up of representatives of producers, consumers and general interests, and so selected that all interests concerned have adequate representation on the section committee.

It is understood that a standard must be referred to as that of the sponsor, using whatever title the sponsor has given it, followed by the statement: "Approved by the American Engineering Standards Committee." The approval may be given in one of three ways: Recommended practice, tentative standard, or American standard.

Any standard or group of standards adopted by any organization or in process of preparation prior to January 1, 1920, may be approved by the committee, if in the opinion of the committee it has either been developed by a properly constituted committee, or has, by actual practice, proven its right to become a standard.

In addition to the work of assistant in the selection of committees and certifying that their work has been done under proper conditions, the committee will act as a bureau of information regarding standardization. It will collect information regarding existing standards and as to the bodies that have formulated or adopted them. This will enable it to properly give the data to those who select a committee to formulate a new standard or revise an old one.

Provision is made for direct representation on the American Engineering Standards Committee, of additional organizations (or groups of organizations) interested in engineering standardization. Already several important additional organizations of national standing have applied for membership on the committee.

The Operation of Pump and Injectors

The Following Article Gives Information Regarding Pump Principles and Operation Which Should Prove to be of Interest to the Tyro Desiring a Knowledge of the Subject

By LLEWELYN

PUMPS may be divided into several classes, reciprocating, rotary, and centrifugal. Those of the reciprocating class which have one or, more cylinders are named simple, duplex, triplex, etc., according to the number of cylinders. Some are single acting, others double, that is, they either force water into the boiler or discharge pipe during one or, both strokes. They may be horizontal, or vertical, belt driven, gear driven or connected direct to a steam cylinder. Some pumps have pistons, others plungers.

Our young men who are preparing themselves for their examination, to obtain a certificate, will do well to get all the information they can on pumps. The boiler feed pump is one of the most important things in the boiler room, and

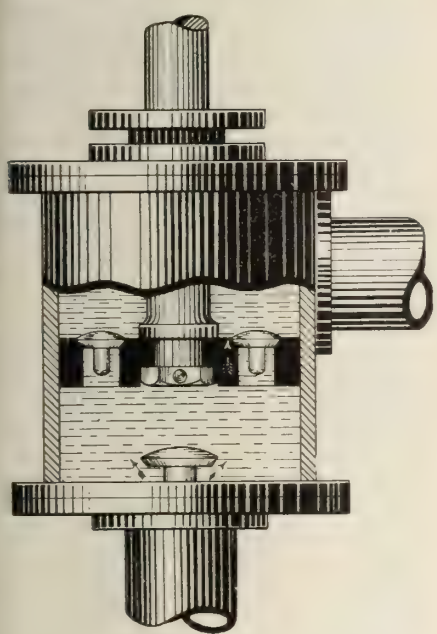

Fig 1

should be thoroughly understood, not only boiler feed pumps but every kind, suction, lifting, force pumps, etc. Examiners, as a rule, shoot over quite a number of interesting questions in regard to pumps in general.

A suction pump is shown in Fig. 1. You will notice that it has a valve of the non-return type in the suction pipe, and one or more similar valves in the piston, or bucket as it is sometimes called.

Do not tell the examiner that a suction pump works by suction unless you understand just what is meant by suction. Webster, in the Collegiate Dictionary, says. "Suction is drawing by exhausting the air."

In the type of pump shown in Fig. 1., the piston with the valves closed on the suction stroke forms a partial vacuum behind it in the cylinder and the pressure of the atmosphere causes the water to rise in the suction pipe through the suction valve into the cylinder. At the end of the stroke the piston starts to descend, closing the suction valve, and forcing the water through the valves in the piston. On the next stroke the water that has passed through the piston is discharged through the discharge pipe, the piston at the same time is now making its second suction stroke, and so on.

An important point to bear in mind is that the pressure of the atmosphere will only sustain a column of water a certain height, hence, it follows that the greatest distance that the piston should be (when at the top of its stroke) from the surface of the water is about 28 feet, though the atmosphere is said to balance a column of water some 33 feet in height, allowance must be made for any air leaking through the valves, the weight of the suction valve, etc.

If it is necessary to raise water from a greater distance, a lifting pump is used, the action of which is the same as the suction pump, with the addition of a non-return valve in the discharge pipe, to prevent the return of the water. The pump itself is located within the 28 feet from the water and the delivery pipe brought up to the height where the water is to be discharged.

The action of a suction pump and lifting pump are practically the same and are generally considered separate simply because the suction pump discharges at the pump level, and the lifting pump above the level of the pump.

Another form of pump is the force pump, Fig. 2 and 3, which has no valves in the piston but on the suction and delivery. A plunger instead of a piston or bucket is used when it is necessary to force water against heavy pressure, this obviates the necessity of keeping a water-tight piston which is difficult to do against high pressure.

The number of different designs and size of pumps on the market are legion and a description of each is not at all necessary as it is the principal upon which they are all based is the important point, and though simple, quite a number of important points occur when in operation.

Boiler feed pumps, in the majority of cases, are direct driven, that is the plunger or piston rod from the pump is connected on the opposite end to a piston working in a steam cylinder, and may be single cylinder, duplex or multiplex. A duplex pump which is used extensively consists of two steam cylinders and two water cylinders. The steam valves on the one side are operated from the opposite side and vice versa. The suction and delivery pipes are common to both pumps.

The chief points in considering a boiler feed pump are, that they should be large enough, having a capacity of at least 1 cub. foot of water per horsepower per hour, should be quiet in operation, economical in steam consumption, have no dead centres, and as few parts as possible.

If the suction pipe is long it should be provided with a foot valve on the end just above the strainer. Both suction and delivery pipes should be kept as large as the openings in the pump permit, should be free as possible from bends, and all joints well made, especially on the suction pipe, for if these are not air tight, trouble will be the result.

In fact, providing there is a good

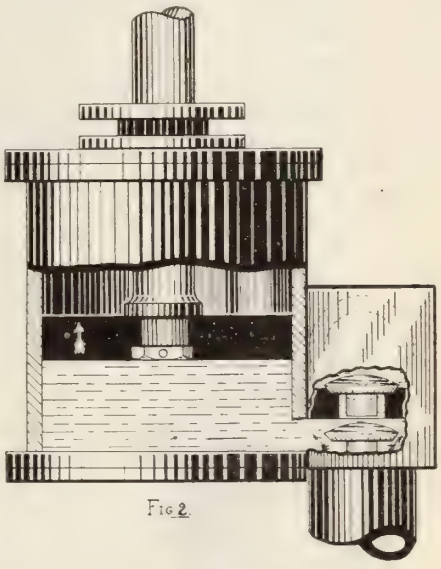

Fig 2

supply of water and sufficient power to move the plunger a pump fails because of one thing only, and that is, there is a leak somewhere, either in the suction pipe, in one or more of the valves, or the piston, etc. It is very important that you locate the trouble quickly when your pump fails. By opening the petcock on the side near the bottom of the pump and noticing if water is discharged through it on the discharge stroke only, or both suction and discharge strokes, or on neither suction and discharge. If on neither stroke your pump is not getting water, either through a leaky suction pipe, leaky piston, suction valves may be stuck, or the supply shut off, or water too low in the well. Again, if you get a good force of water at both strokes your check valve and discharge valve may be leaking or prevented from returning to their seats for some reasons,

perhaps some foreign substance is lodged on the seat, such as a match stem, chip of wood, piece of old packing, etc. If your water is too hot your pump is almost sure to give trouble, if not fail altogether by becoming steam bound, as a pump will not lift hot water but generally pounds badly, and the partial vacuum formed by the plunger is immediately destroyed by the vapor occupying the space.

If it is necessary to pump hot water then have the pump so located that the water will flow into the valve chamber, that is, put the pump below the source of supply.

A suction air chamber is a useful addition if the suction pipe is long or the pump is running at high speed, as it not only prevents pounding but assists in enabling the pump barrel to fill up when running at high speed.

A suction air chamber can easily be made with a piece of pipe the same size as the suction pipe, about two or three feet long, with a cap on top, attached in an upright position to the suction pipe close to the pump.

The delivery air chamber, which should not be less than about five times the area of the water cylinder, also assists the pump by virtue of the air compressed there in forming a cushion, which acts on the delivery valves and also causes a more steady flow in the discharge.

For good results the velocity of flow in the suction pipes of boiler feed pumps should not exceed about 200 feet per minute for small pumps. 400 feet per

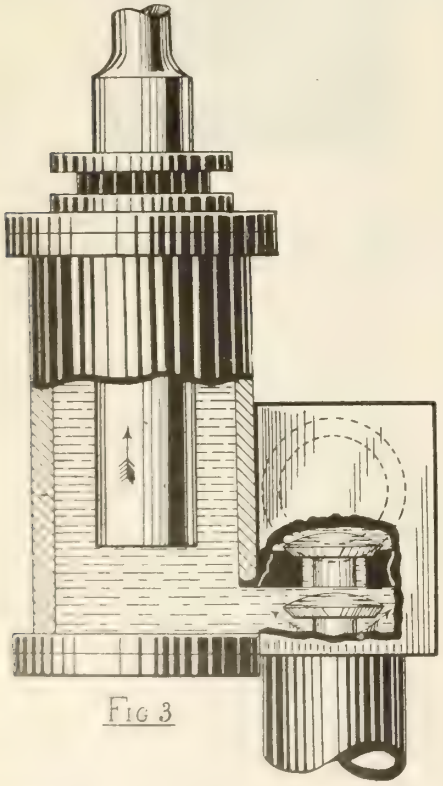

FIG 3

minute for a single cylinder, and 500 feet per minute for a duplex pump.

In calculating the power for a pump the number of foot pounds of work to be done by the pump must be considered, the boiler pressure it has to work against, the suction lift, and an allowance made for friction, etc. The suction lift being known, convert the boiler pressure into its equivalent head of water in feet by multiplying it by 2.31 and add to the suction lift, then, with the weight of water to be pumped, the foot pounds of work to be done can easily be calculated. As an example, a boiler has a pressure of 100 pounds per square inch, and the suction lift is 15 feet; you wish to find what horsepower it will take to put in 625 gallons. Then $2.31 \times 100 + 20 = 251$ feet head; 625 Imperial gallons weigh 6,250 pounds, and $251 \times 6{,}250 = 1{,}568{,}750$ foot pounds. One horsepower = 33,000 foot pounds; $1{,}568{,}750 \div 33{,}000 = 47.54$ horsepower nearly; allowing 25 per cent. for friction, etc., $47.54 + 25$ per cent. $= 59.425$ horsepower. That is to do the work in one minute. If one hour is taken to do the work it will require $\frac{1}{60}$ the power, or about 1 horsepower.

Again, if you wish to find the size of feed pipe required for a boiler when a duplex pump is used, allowing a velocity of 500 feet per minute, divide the velocity, viz., 500 into 19.25 times the number of gallons per minute for U. S. gallons, or 23.1 for Imperial gallons. Thus, to pump 50 U. S. gallons into a boiler a minute, $19.25 \times 50 \div 500 = 1.925$ sq. inches area of pipe.

And further, to find the number of gallons passing through a pipe in one minute, multiply the velocity in feet per minute by the area of the pipe in square miles and divide by 19.25 or 23.1 as the case may be.

The velocity of flow may be found by multiplying the area of the water piston by its speed and divide this by the area of pipe.

In the Province of Ontario it is necessary to have two separate means of supplying feed water (Sec. 121), and the injector is used to such an extent that the student should be cognizant of its general principles. Fig. 4 shows one form which will serve our purpose for the present.

The action of the injector is based on the fact that the amount of work a moving body can do in being brought to rest varies as the square of the velocity.

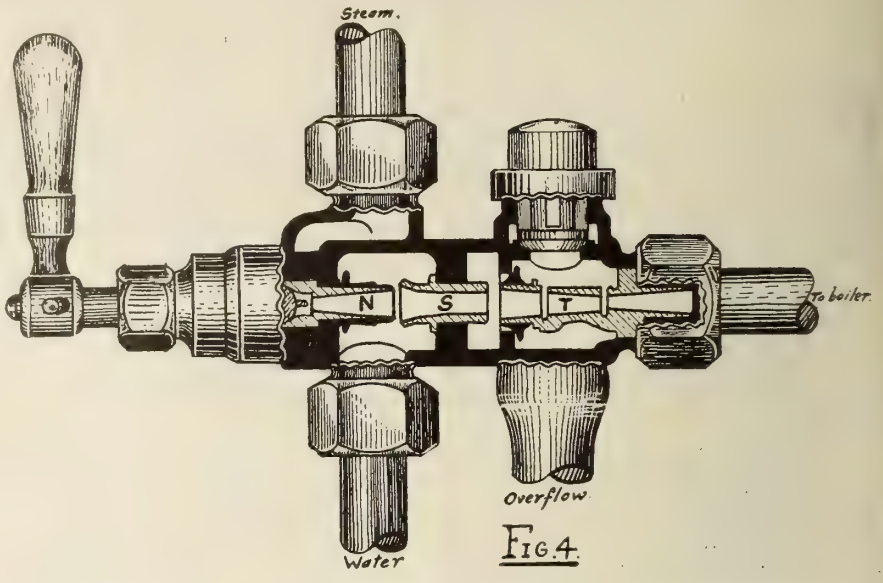

FIG 4

The steam from the boiler in passing through the steam nozzle N has its pressure reduced, first owing to the shape of the nozzle and second by coming in contact with water of a low temperature. This immediately gives the steam a high velocity and great kinetic energy, which creates a partial vacuum in the water space, inducing the water to pass through the suction jet S on to the delivery tube T with sufficient force to overcome the resistance of the boiler pressure in the feed pipe.

It is evident that unless the steam is condensed the injector will not work, and much trouble with injectors is caused either by giving the injectors too much steam, especially if the pressure and consequent temperature is high, or, if the feedwater is too hot, unless you throttle the steam a little.

Like pumps, injectors are affected in various ways—a leaky suction, too hot feed water, or the flow retarded by an accumulation of mineral deposit from the feed water.

It is important in the operation of an injector that the size of jet remains unaltered, this size is determined in the first place by the manufacturer, and much trouble has been caused by carelessly reaming or scraping the jet to remove the scale deposit, making the jet much too large, thus reducing the efficiency. It is far better to use a solvent to remove the scale such as dilute muriatic acid or some other scale remover.

An injector is a good way of feeding a boiler providing that a suitable one is selected for the condition under which it has to work, and care is exercised not to subject it to careless treatment.

Injectors are also used for many purposes beside feeding boilers, such as raising water from excavations during construction work and in mines for draining certain places, etc.

The Stationary Engineer, His Position and Future

The Following Article Gives a Clear Resume of the Present Trend of Engineering Practice and of Future Developments. The Various Means by Which the Engineer Can Keep Abreast of the Changing Knowledge Required of Him Are Also Indicated

By M. B. WATSON, M.E., Director of Engineering, Toronto Technical Schools

THE progressive advertising and educational campaign of the Electrical interests in this country, and especially in Ontario, has resulted in the scrapping of many of the stationary steam plants during the past decade. If this electrical replacement of steam power continues for the next decade, as it seems likely to do, it would appear that a large number of the steam engines now operating will be lying idle or sold for scrap, while their boilers may be used to a limited capacity for heating in the winter season. When this condition comes how are the large number of stationary engineers, now operating engines going to be employed? The positions to which they are promoted, or drift back, are dependent in each case on the individual characteristics and capabilities of the engineer.

The engineer, or more properly engine driver, who can not take charge of responsible work other than in connection with his steam plant, will naturally be left in charge of the boilers as far as they are used, and as they will likely be used only for heating purposes, he will probably have charge of the radiators, ventilating fans, etc., but is this the kind of work an engineer wants? This amounts to becoming an assistant janitor, and naturally is not as important a position as he holds at present and consequently will not demand as high a salary. No. The real engineer does not want this kind of a position. He wants a real job with big responsibilities; not helping out with any sort of odd job except in the heating season.

The reasons for the imminent replacement of a large amount of steam power are obvious. Some of them are: The relative cost, especially in the small and medium sized plants, is greatly in favour of electricity in most localities. The uncertainty of adequate fuel supplies and the instability of its cost. The cleanliness, convenience and sightliness of electrical distribution systems and individual drives for machines, as compared with the mechanical distribution of power, and the saving of power incidental thereto. The immediate availability of any part or the whole of the load capacity, independent of conditions in the boiler room or other parts of the factory .

The above advantages can not be disputed, but many of them may be qualified to a certain extent as follows: In the matter of cost it may be shown that where low pressure steam is required for heating or manufacturing purposes, power can be generated by steam, using the exhaust for the above purposes, at a lower cost than it can be purchased in most districts. As to the uncertainty of fuel supply, fuel must be used for heating in any case. With exhaust steam heating systems, less than five per cent. of the heat value of the steam is used in the generation of power, thus if this system is used less than five per cent. extra fuel will be required than will have to be purchased in any case. The cleanliness etc. of electrical systems can be retained where the steam engines are used to drive electric generators, and the electrical distribution and individual drive be used. As to availability, during the heating season steam must be kept up in any case thus having the power instantaneously available besides, power companies cannot guarantee an absolutely constant supply of power on account of accidents, storms, etc. However, let us leave the advantage with the electrical system. How can the present engineer be employed to escape becoming a janitor or handy-man-about-the-place? The supplanting of many steam plants may be inevitable, but the scrapping of engineers is not.

The word ENGINEER is derived from the latin word ingenium meaning ability and skill in invention or production. From the same source comes the word ingenious. Thus a real engineer must have ability, skill and ingenuity. If he has these qualities when his steam plant is closed down he will be able to take charge of any or all of the following work. The complete charge of the heating system and the ventilation, this requires a complete knowledge of the principles upon which the complete systems and each part work. Having this knowledge, he can at once locate and remedy trouble, or could design and install correctly a similar system. This means that he will be in a position to take charge of extensions or changes for his employers, instead of calling in outside experts, as probably would have been done if he were still occupied operating engines. He should also be competent to take complete charge of the electrical system in the plant, to repair same or install additional equipment, and be able to advise his employers intelligently regarding requirements, sizes etc. of equipment. This requires a fair knowledge of electrical construction and electrical machinery, also any government or underwriter's regulations under which same may be operated. In refrigerating plants, he must understand their principle as well as their operation to efficiently take charge of their repair, extension or alteration etc., without outside expert assistance. He should be able to calculate their capacities and give reliable advice regarding extensions etc. to architects, employers, etc. He should have a good understanding of general machinery and machine work, that he may be able to look after the operation and maintenance of any types of machinery used in his plant. He should as well be able to estimate closely the labor and materials required for extensions or alterations in his part of the plant, and to offer sound advice on the selection and purchase of further equipment. If the engineer can prove to his employers that they might save a great deal of power and money by continuing to operate the steam plant, especially in the winter, he is not only saving money for the firm, but assisting in the conservation of the country's resources, and strengthening his own position with his employers as well as helping the power companies over their peak load season which is caused in the winter by the overlapping of the lighting and power loads, and the large amount of electric heating employed.

Thus it appears that the engineer who anticipates this change or power conditions, and who prepares himself to handle expeditiously duties such as those mentioned above, will be given more authority, responsibility and salary, instead of drifting into a mere coal heaver and handy-man.

In the Province of Ontario, in view of the recently enforced Regulations respecting the grading of Stationary Engineers, many of these engineers must do considerable studying to retain as good or better positions as they now hold. While doing this it would be folly to overlook the prospects for the future, and do only sufficient studying to pass the examinations. Engineers must keep it up in order to progress and become a recognized standard among engineers of the world.

To accomplish this result it is up to each individual engineer to get out after the required education and training. There are numerous ways of doing this. The practical work required can be got on your own job or in your own factory; but to understand the principles and apply them scientifically to your work, a certain amount of technical information is necessary. This technical knowledge can be got privately from books, or much more easily at one of the Technical schools of night classes throughout the country, or by correspondence courses from the better Engineering colleges. The technical press is also one of the

greatest aids the engineer can have in the educating of himself for better things.

It can be seen from the above that to get along an engineer must have a complete fund of engineering knowledge at hand and the power to apply this knowledge to his own problems. How many of the stationary engineers in this country could successfully carry out work as suggested above? The answer would be a very small proportion. This condition can only be remedied by a comprehensive scheme of practical and technical education, but the engineers must come after it. It will not hunt them out and force itself on them. It is generally understood that the authorities controlling the above conditions and preparing for it by requiring a more general and diversified knowledge of engineering and a larger amount of business ability and technical training. It is thus those who apply themselves, and do more work than they are actually paid for in so many hours in the engine room, who will progress when the number of qualified steam engine operators is in excess of the demand.

Reader's Query

WE have received a request for information concerning the horsepower of an engine flywheel. Before entering into the mathematical side of the question it may be well to define the two terms horsepower and energy, for they are not synonymous, and the use of the term horsepower in speaking of a flywheel, except in a very restricted sense, is not strictly accurate.

Consider energy first. Energy may be defined as the capacity for doing work, and in speaking of material objects this energy is inherent in the object by reason of its position in space or by virtue of its velocity. Intimately associated with energy is also the idea of force. Force in some cases may be due to the weight of an object as when we say a pound weight exerts a force of one pound on a table or other support, or force may mean the stress in a body as when we say a belt has a tension of so many pounds.

It is now possible to examine what is meant by the term energy, and when energy is considered it may also be well to consider the term work. Let us suppose we have a weight of one pound resting on the floor and that we raise this weight three feet and place it on a table. We have done two things: first of all we have done some work on the object in raising it the three feet. The work done is simply defined by the product of the amount of weight lifted and the distance through which it has been raised in this case the work done will be three foot-pounds, a compound unit.

We have also increased the available energy of the weight for we have placed it in a position where it is capable of doing more work. If it were pushed off the table it would do work on the floor, denting it and making a noise. The amount of energy we have added to the weight equals the work done, or three foot-pounds. To this type of energy the name potential energy is given, since it has a capacity for doing work when conditions are right for the release of the energy.

Other forms of potential energy will occur to the reader: explosives, a steam boiler under pressure, a lake at a considerable elevation, etc.

Another form of energy is possessed by a moving body, since by reason of its weight and velocity it is capable of doing work. Our one pound weight will here again serve as an example. At the instant of starting to fall off the three-foot table it possesses three foot-pounds of potential energy and no kinetic energy. When it has fallen one foot it only possesses two foot-pounds of potential energy (since it has two more feet to fall) and one foot-pound of kinetic energy. At the instant of striking the floor and before its velocity is destroyed it possesses no potential energy and three foot-pounds of kinetic energy. When it has hit the floor no energy of any kind remains, and work to the extent of three foot-pounds has been done.

Work may be defined as force through distance, since if a piston works through three feet against a pressure of 1,000 pounds, work to the extent of 1,000 x 3 = 3,000 foot-pounds has been done. So far we have only considered two things, force and distance, and when we speak of power we must take heed of a third—time.

We might do 3,000 foot-pounds of work in sixty minutes, or it might take us just one. In the latter case the power exerted would be just sixty times that in the former.

Power is time rate of working and always includes the idea of work (foot-pounds) and time. When we speak of horsepower we are speaking of a particular unit devised by Watt for power measurement. One horsepower simply means the doing of 33,000 foot-pounds of work in one minute, or 550 foot-pounds in one second.

A fly-wheel acts as a store house of energy, and in doing so, serves to smooth out the speed of an engine. During a certain portion of the stroke, in passing the dead centres, the flywheel uses some of its energy in doing work and maintaining the speed of the engine nearly constant. This work is done at the expense of its own speed and it slows down slightly. When the expansive force of the steam comes into play, the flywheel is speeded up, work is done upon it and energy is stored up in it.

It would be quite possible to say that the flywheel has a certain horsepower which is exerted at some parts of its revolution but the term would have little meaning and calculations as to the weight necessary are more simply made without the definite use of the term horsepower.

It would also be quite correct to say that the flywheel would have a certain horsepower if the steam were cut off and the engine allowed to slow down under the action of the flywheel. But under running conditions the flywheel is not an instrument or mechanism for supplying power beyond the engine. Its only use is to smooth out the fluctuations in the power supplied by the piston and to make operation possible and the speed more uniform.

The stored energy of a flywheel is a perfectly definite quantity and depends upon its weight, speed and the disposition of the weight in the flywheel. Heretofore we have been dealing with height or distance fallen through instead of velocity when speaking of energy and the introduction of velocity complicates matters somewhat.

A falling body under the influence of gravity always has a certain velocity at each instant through its flight and this velocity varies continuously, increasing all the time. This is due to the force of gravity which accelerates the velocity according to a definite law. The relations between the different properties of a falling body are all expressed by means of a few simple equations and in these the weight of the body has no influence whatever.

If we know the velocity which a body has at any instant we can easily find out the distance it must have fallen through to attain that velocity. In the case of a rotating body it is also possible to figure out by the same equation what distance a portion of the flywheel or other body would have to fall to attain the same velocity.

The equation referred to is:

$$h = \frac{v^2}{2g}$$

where h = the height in feet fallen through
v = the velocity in feet per second
g = the acceleration due to gravity = a constant which may be taken as 32.2.

To find the energy stored in a moving body it is only necessary to multiply the value for (h) found above by the weight in pounds and the result will be expressed in foot pounds or

$$E = \frac{wv^2}{2g}$$

where E = energy in foot pounds
W = weight in pounds
and the other units are as before.

This formulae applies without change to the case of a body moving in a straight line but when applied to a flywheel certain reservations are necessary.

These have to do with the velocity v^2. It might be asked where this velocity were to be taken—whether at the face of the wheel, the average radius of the rim or elsewhere, for all points on any radius are moving at different velocities. Again the disposition of the weight affects the problem somewhat, since the same weight concentrated in a heavy rim would be of more value than if distributed throughout a lighter rim and heavier arms. This is

the case and to enable these factors to be taken into account formulae are derived which take these factors into consideration (see Kent, 9th Edition, page 529)

As an approximation, we may take the formulae given above and may assume W = to the weight of the rim; $\sqrt{}$ = to the velocity of the flywheel at its mean radius and the remaining symbols as before. Their own result will be fairly close to the correct result for the stored-up energy in a flywheel.

Operating Features of Carbon Dioxide Recorders

THE most insidious and possibly the greatest single cause of waste of fuel in the ordinary boiler plant is the excessive amount of air which usually finds its way into the furnaces and other parts of the boiler setting. The reduction of pressure inside the setting due to the chimney draught causes the cold air to rush in through every crack and crevice it can find, and it even filters through ordinary brickwork in appreciable quantity. The consequence is that far more enters than is necessary for the proper combustion of the fuel, and this excess air lowers the furnace temperature, absorbs heat which should be given up to the boiler, and goes up the chimney, carrying away this heat to waste. Further than this, it spoils the draught both by cooling the flue gases and increasing the chimney resistance. Its harmful effects upon economy are frequently overlooked because its presence is invisible, yet so serious are they that in most boiler plants a very material saving of fuel might be effected by a proper attention to the exclusion of superfluous air.

While much may be done by the exercise of common sense, in filling up cracks in the boiler setting, making air-tight joints between the brickwork and the boiler drums, seeing that inspection doors are tight, that excess air cannot get in around mechanical stokers, and in the numerous other ways which will occur to everyone familiar with boilers, experience shows that the best results cannot be obtained without some means of determining whether the efforts made are really adequate. The crucial test is the composition of the flue gases leaving the boiler. If these are diluted with air, it is clear that excess air is entering the setting, and many an engineer who prides himself upon the condition of his boiler plant has been disagreeably surprised at the unsuspected air leakages which a test of his flue gases has disclosed.

Composition of Flue Gases

If the combustible portion of coal consisted of carbon only, and if exactly the proper amount of air were supplied for combustion, it is obvious that the flue gases would contain 21 per cent. by volume of carbon dioxide, as this is the percentage volume of oxygen contained in the air. But account must be taken of the hydrogen contained in the hydro carbons, which also requires oxygen for its combustion. If the hydrogen content is taken at 5 per cent., which is about the figure for bituminous coals, we shall have oxygen equivalent to only about 18 per cent. of the air available for the burning of carbon, so that 18 per cent. may be considered as the maximum possible percentage of carbon dioxide which can be obtained with ordinary coal. The remaining 82 per cent. of the flue gases would be composed of nitrogen and water vapor.

Combustion as efficient as this is, however, impossible of attainment in practice because owing to the physical nature of the fuel-bed, a certain excess of oxygen is necessary to prevent some of the carbon dioxide from being reduced to monoxide in its passage through the bed and passing away as such in the flue gases. This incomplete combustion must be avoided because it involves a very serious waste of fuel, a pound of carbon producing only about 4.350 B.t.u. when burnt to monoxide, as compared with 14,540 B.t.u. when burnt to dioxide. The problem before the engineer is to limit his air supply to the smallest amount compatible with the absence of carbon monoxide from the flue gases, as every cubic foot of air more than is absolutely necessary serves only to cool the boiler and to spoil the draught.

The Orsat Apparatus

There has been on the market for many years an apparatus by which a simultaneous determination of the principal constituents of the flue gas may be readily made. The Orsat apparatus, as it is called, consists of three glass vessels containing solutions which will absorb respectively carbon dioxide, oxygen and carbon monoxide. A sample of the flue gas is brought into contact with the various solutions, and the percentage of each of the constituents named can be read from the height of liquid in a graduated tube. This apparatus gives invaluable quantitative information as to what the conditions are when the test is taken. The presence of carbon monoxide indicates too little air for proper combustion, while that of free oxygen denotes that more air than necessary is passing through the furnace. The highest percentage of dioxide which is consistent wtih the absence of monoxide is the ideal to be aimed at, and when once this is determined the conditions which provide it should be maintained continuously as far as is possible. The state of the fire and the quantity of air passing through it, are, however, changing constantly, and it would be quite impracticable to keep a continuous check upon efficiency by means of an Orsat apparatus. Something much simpler is necessary for practical use, and a large number of instruments have been developed which will automatically test the quality of the flue gases and make a continuous graphic record of the percentage of carbon dioxide they contain.

All the instruments on the market depend for their operation upon the principle of absorbing the dioxide from a sample of the flue gas, usually by means of a solution of caustic potash, which has a great affinity for carbonic acid. Sometimes the caustic potash is used in the solid form, while in one instrument its place is taken by ordinary quicklime, which has similar absorbent properties. The methods by which the sample of gas is measured and brought into contact with the absorbent vary considerably. A common device is to allow a flow of water to trickle continuously into the instrument. When a container becomes full it is suddenly emptied by a siphon action, and draws in a measured sample of the flue gas. This is then automatically put into communication with the chamber containing the caustic solution, and the sudden diminution of its volume, due to the absorption of the dioxide, is measured by the descent of a kind of gas-holder in which it is contained. The motion of the gas-holder causes a pen to draw a line on a chart, the length of the line being proportioned to the percentage of dioxide. This cycle of operations takes place every few minutes, according to the rate of the flow of water.

Instead of measuring the diminution in volume corresponding to the dioxide which is absorbed, some inventors have utilized the reduction of pressure caused by the absorption to indicate the percentage present. A small current of flue gas is continuously drawn through a chamber containing the absorbent by means of a steam jet aspirator. The elimination of dioxide causes a reduction of pressure in the chamber, which is measured by a manometer or any suitable form of pressure gauge. This method provides a continuous record, and has also the advantage that the recording instrument may be situated at any reasonable distance from the boiler-room if desired. An alternative plan is to draw the flue gases through a chamber in which the absorbent is covered by a porous pot. The reduction of pressure inside the porous pot is then utilized to work the manometer. In both these types, however, the consumption of the absorbent is greater than when an intermittent test only is made, and the use of a steam jet is also regarded as wasteful.

Yet a third principle of determining the carbon dioxide contents has been developed, which is attractive in some respects. In place of measuring either the shrinkage of volume, at constant pressure, of the drop of pressure at constant volume when the dioxide is removed, the flue gas is passed through two ordinary gas meters, one before absorption and one after. The second one will work more slowly as it has naturally less to measure. The difference in their speed is recorded by a differential gear which operates the pen producing the record. In this type of instrument dry calcium hydrate forms the absorbent, and the gases are drawn through the meters by a water jet.

It is by no means unusual to find a boiler plant being operated with not

Fuel Alcohol

IT has been said that the fuel resources of the world both as regards coal and oil are sufficient unto the present day and that regard for the comfort and convenience of future generations is a bit too altruistic. In other words we should trust to a kind Providence or to man's ingenuity and inventiveness for the circumventing of a future shortage of coal. While this is true and while it is also true that the present known resources in the way of coal and oil will last for some little time to come it is also true that long before exhaustion takes place, prices will have advanced to such a point as to render conservation in the strictest sense advisable.

To-day even coal and oil are far more expensive than anyone thought possible a few years ago and increasing attention is being given to other forms of fuel.

Low grade lignites and other material formerly of little value are now being used and industrial alcohol is being recognized as a cheap and valuable fuel for the internal combustion engine. The Advisory Research Council in Canada published a report on the use of industrial alcohol some little time ago and a recent report states that the Dominion Government is contemplating the removal of restrictions on its manufacture and will free it from excise duties.

The importance of this step can scarcely be overestimated, for the production of alcohol may be likened to the use of our waterpowers—water over the dam is lost forever and undeveloped waterpowers have to be paid for in the use of fuels which when once mined can never be replaced. In like manner the raw materials from which the alcohol can be obtained are now wasted, wood waste is allowed to rot or is burned, vegetable waste of the farm or city garbage is treated similarly and the sulphite liquor of the pulp mill is turned into the nearest stream to the pollution of the waters and the injury of all aqueous life. This latter source of alcohol, in passing, would provide an enormous quantity of alcohol for industrial purposes at a very reasonable price.

Probably the greatest immediate use for alcohol would be in the form of motor spirit and in this alone its use would render Canada more self contained, rendering her independent of foreign sources of supply, incidentally to the material benefit of the exchange situation. Tests have shown that alcohol is an admirable source of heat energy and any engine at present using gasoline may be run equally well on alcohol, although an increase in power of about 20 per cent. can be obtained by redesigning.

An interesting feature in connection with the world-wide shortage of fuel is the appointment in England of Sir Frederic Nathan as power alcohol investigation officer under the Fuel Research Board.

Suggestions For Improvements

From the suggestions sent us in response to the request for constructive criticisms of the Act, several facts stand out very clearly. No objection is made to the first class certificate requirements insofar as technical knowledge is concerned but some adverse comment has been made regarding the length of service necessary. This might be shortened possibly to the advantage of all concerned but it at least assumes the attainment of practical knowledge of sufficient extent to balance the technical knowledge required.

The greater objection to the Act seems to be in connection with the requirements for first class engineers, the size of plant operated by the second class man and other relationships between these two grades. That is to say, the practical engineer, up in years, argues with every appearance of right that he will be unable to operate a plant of any size since he has not the technical training to pass the first class examinations.

A remedy has been suggested, the lowering of the first class requirements. This is objectionable and is a course that meets with the approval of few engineers. Another suggestion, and one which we think has a lot to commend it, proposes that the plant size be raised for the second class engineer. In this case he would be able to take charge of power plants up to say, for a guess, 2,000 boiler horsepower. This would do justice to the engineer, maintain the high standard of the first class certificate and would be the best all round solution.

In any case changes and improvements of this nature can only come after the Act has been in force for some time and experience has been gained as to its effectiveness.

"CAN any of you tell me what the late ruler of Russia was called?" asked the teacher. "The Czar!" roared the class. "And what was the Czar's wife known as?" Only two voices answered this time: "The Czarina." "Ah!" said the teacher eyeing his flock fondly. "That is very good. Now, who will tell me what the Czar's children were called?" "Czardines!" yelled one little boy.

How the Locomotive Whistle Came to Life

A Musical Instrument Maker Solved the Problem—Horseback Rider Used to Precede the Locomotive

By F. A. McLEAN

SURROUNDED on every side by wonders of the mechanical and electrical world, the majority of people are disposed to take them for granted and regard them more or less as if they had always been. As a matter of fact, there is usually an interesting story behind the invention of most of the things that are now considered essential to our everyday life.

How many people, for instance, could tell offhand who invented the locomotive whistle or know that it came into being like many other epoch-making inventions and discoveries as the result of an accident. An apple falling on the head of Sir Isaac Newton, as he lay under a tree, is said to have started the train of thought which led to the promulgation of Newton's law. Bell stumbled onto the telephone accidentally while working on an apparatus to improve the hearing of the deaf. The phonograph was born while Edison was working on an entirely different invention. A lazy boy gave us the first automatic valve motion for a steam engine, while Elias Howe is said to have conceived the sewing machine needle in a dream, so that it is not at all strange that the invention of the locomotive whistle was also brought about by an accident.

On May 4th, in the year 1833, Stephenson's locomotive the "Samson"—a successor of the famous "Rocket"—ran into a farmer's wagon containing fifty pounds of butter and eighty dozen eggs, on a level crossing between Thornton and Bagworth, England. Had the high cost of living been a topic of discussion at that time, or had butter and eggs been worth as much in those days as they are now, perhaps Stephenson's career as a railroad builder would have been cut short.

At any rate, as a result of this spreading of butter and eggs around the landscape (and perhaps as an aftermath of the death of William Huskisson, a Cabinet Minister, who was killed by Stephenson's Rocket on September 15th, 1830, and thus had the unfortunate record of being the first man ever killed by a locomotive) a meeting of the directors of the railroad was called to see what steps could be taken to prevent accidents in the future.

In 1825, when the Stockton and Darlington Railway was opened, for the first part of the trip, a man on horseback had preceded the locomotive, warning people to get out of the way, but during the latter portion of the trip Stephenson ordered him out of the way and speeded his engine up to fifteen miles an hour. The Samson being a heavier and more powerful locomotive than the famous Rocket and other earlier models, sending a mounted man ahead of it was now out of the question, so Stephenson's suggestion that a whistle blown by steam could be used, was welcomed by the directors.

Acting on Stephenson's advice, a musical instrument-maker in the town of Leicester produced a steam trumpet which was about eighteen inches long and about six inches across the bell, and resembled a huntsman's horn. This horn was tried out before the board of directors and accepted. It must have had a weird sound, and no doubt was effective, as we are told that the Reverend Sydney Smith, a witty divine, was wont to say that "Stephenson's whistle always reminded him of the squeal of a lawyer when the De'il first got hold of him."

The Tunnel Will Be Built

FOR years engineers have talked of the day when the tunnel would be completed between England and France. The world in general has not been much interested, probably because the world in general never thought such a thing practicable.

But work is going to start—start from both sides, the French and English Governments to find an equal share of the money and provide an equal share of the men.

Then it will be possible to take a train at London for Constantinople, for any European capital. Through the tunnel the line will be run by electric power. This will prevent trouble with engine fumes, which was one of the serious objections to the long tunnel through the Alps.

Forty-five minutes will be occupied in going through the Channel tunnel. Passengers, in fact, will pass through the tunnel almost without realizing they are passing under stormy Straits.

The tunnel will be about thirty miles long. It will not be exactly in a straight line. Beginning at a spot two or three miles on the island side of Dover, it will follow the gray chalk bed of the Channel, which is impervious to water and suitable for tunnel construction, and come out at a point between Calais and Boulogne, near the village of Marquise.

There will be, as on the London underground railways, two distinct tubes. Below them, about nine feet in diameter, will be a drainage tunnel. The whole work will take five years to complete and will employ 1,200 men on each side.

The French, who are proud of their share in the tunnel, will do half the work and find half the money. There is bound to be much friendly rivalry between the two sections of workers as to which will go ahead the faster.

According to exact calculations of the engineers, the French and British workers, who will begin construction of the tunnel thirty miles apart, will meet within an inch or two of the centre of the tunnel.

THE QUESTION IS—"WHEN WILL THEY GET DIZZY?"

Progress in New Equipment

NEW ELECTRIC RIVET HEATER

THE ordinary method of heating rivets in the rivet forge is open to several serious objections, and has disadvantages which can't be very well overcome. These objections to the old heating methods with the attendant expense of handling fuels or installation and maintenance of piping, together with the problem of waste gases, cinders and dust are eliminated in a new electric rivet heater recently developed by the Canadian General Electric Co.

No time is lost in starting production, since the first rivet is heated in a few seconds after throwing the switch. In ordinary methods of heating rivets the heat is applied from the outside, and the rivet may in consequence be cooler in the interior than good driving would allow. In the new electric heater the rivet is heated from the inside, which gives uniformity of heat and the best upsetting conditions in the shank.

The even quality of the heat produces a minimum amount of scale, and the absence of products of combustion further eliminates scale, etc. The wastage of rivets is reduced to a minimum, and a further economy is apparent in the high efficiency obtained through the localizing of heat in the rivet. Close heat regulation is also obtained, and power is used only when heating rivets.

Rivets from ⅞ in. to 5 in. in length are heated without adjustment. The mechanism is air-cooled and thus is extremely portable. It may readily be mounted on wheels when desirable.

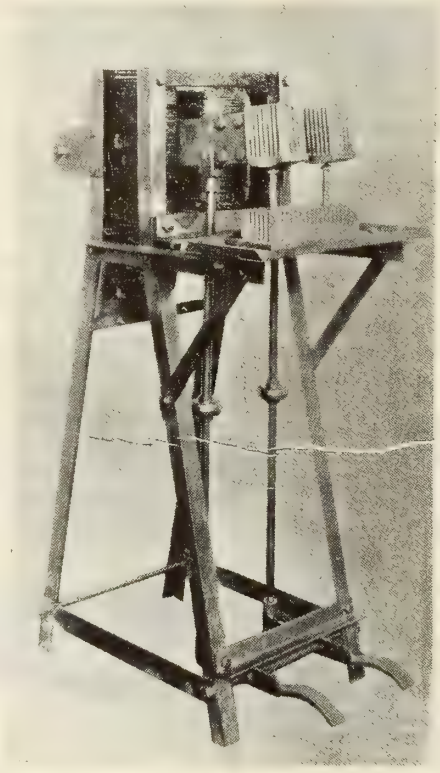
In operation the heater is cleanly, and no smoke results from its use, nor are contaminating gases produced. The heat radiated is also a minimum. The accompanying table gives a fair idea of performance under actual working conditions.

Approximate Maximum Production in Rivets Per Hour on 15 K.W. Machine.

Length under head to point in inches	Diameter in Inches							
	¼	⅜	½	⅝	¾	⅞	1	1¼
1	800	650	550	350	280	190	120	80
2	650	500	400	275	190	130	80	60
3	500	400	300	160	150	100	65	35
4	400	300	250	100	120	90	40	25
5	300	250	200	140	90	60	25	15

Two rivets are heated at one time. The heater will handle rivets up to 1 inch in diameter, and from ½ to 5 inches long. The General Electric Company at Schenectady have heated 500 ½ inch by 1¼ inch rivets with a power consumption of 10 k.w. hours.

It is estimated that this equipment will handle 5 pounds of rivets per k.w. hour. The heater is self-contained and self-cooled, holding two rivets at a time. The rivets are held by placing them in sockets with the transformer, which is a part of the equipment. The wastage of rivets can be reduced to a minimum, for if the machines be left in operation with the rivets in place, it is only necessary to



ELECTRIC RIVET HEATER

burn out one rivet to open the circuit and so prevent further damage. The current consumption is limited strictly to the time the rivets are placed between the electrodes of the heater as the contact is broken as soon as the rivets are removed. Two points worth mentioning are: (1) That the operator might become somewhat alarmed when placing the rivets between the jaws of the heater, because when the heater is closed considerable sparking takes place at the point of contact. This sparking, however, is harmless; (2) the advisability of cleaning the jaws of the heater. Cleaning these off twice a day with an ordinary file is quite sufficient.

Some of the advantages of the heater are that it is noiseless in operation, it is clean, there being no smoke or gases as is present with other methods of heating, no time is lost on operation; after closing the switch it takes but a very few minutes to start work; the voltage across the rivets is but 5 or 6 volts, and therefore harmless to the operator.

Specifications

Height, 4 ft.; space occupied at top, 18 in. square; space occupied at bottom, 24 in. square. Weight approximately, 300 lbs. This equipment can be furnished in 110, 220, 440, 550 volts, 25 and 60 cycle.

Rivet heater will actually heat considerably more than 800 rivets per hour, but this is about the maximum number an operator can handle.

RESEARCH IS BENEFITED

The Carnegie Corporation of New York has announced its purpose to give $5,000,000 for the use of the National Academy of Sciences and the National Research Council. It is understood that a portion of the money will be used to erect in Washington a home of suitable architectural dignity for the two beneficiary organizations. The remainder will be placed in the hands of the academy, which enjoys a federal charter, to be used as a permanent endowment for the National Research Council. This impressive gift is a fitting supplement to Mr. Carnegie's great contributions to science and industry.

The council is a democratic organization based upon some forty of the great scientific and engineering societies of the country, which elect delegates to its constituent divisions. It is not supported or controlled by the Government, differing in this respect from other similar organizations established since the beginning of the war in England, Italy, Japan, Canada, and Australia. It intends, if possible, to achieve in a democracy and by democratic methods, the great scientific results which the Germans achieved by autocratic methods in an autocracy while avoiding the obnoxious features of the autocratic regime.

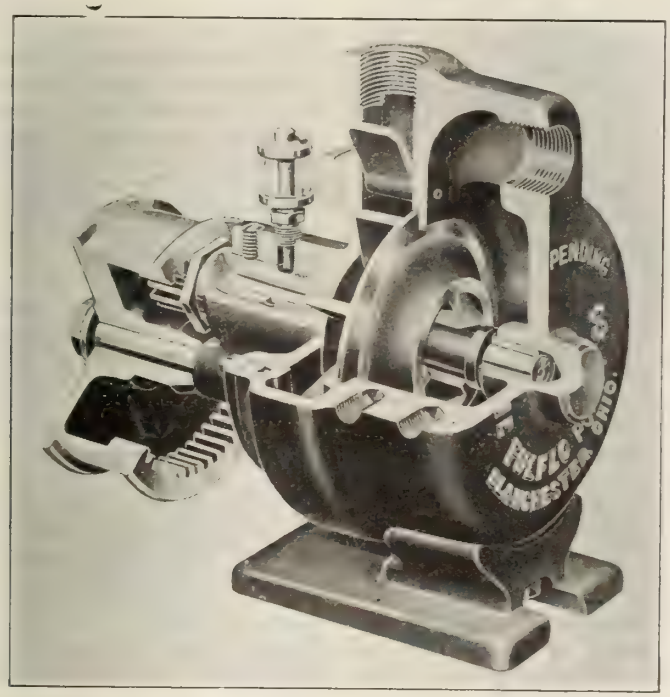
The council was organized in 1916 as a measure of national preparedness, and its efforts during the war were mostly confined to assisting the Government in the solution of pressing war-time problems involving scientific investigation.

Reorganized since the war on a peace-time footing, it is now attempting to stimulate and promote scientific research in agriculture, medicine, and industry, and in every field of pure science. The war afforded a convincing demonstration of the dependence of modern nations upon scientific achievement, and nothing is more certain than that the United States will ultimately fall behind in its competition with the other great peoples of the world unless there be persistent and energetic effort expended to foster scientific discovery.

"FULFLO" REVERSING PUMP

The Fulflo Pump Co., Blanchester, Ohio, has just placed on the market the reversing centrifugal pump illustrated. Its design includes the prime-retaining, non-clogging features of the other pumps of this line with the reversing feature in addition.

The ability to reverse the flow of water or coolant through the pump is obtained through the design of the impeller blades and the introduction of a bronze deflecting gate in the discharge passage. As both openings are at the top of the pump it is always primed and will immediately start the flow of the liquid in either direction, depending on the direction of rotation of the driving pulley.



SECTION VIEW OF THE FULFLO REVERSING PUMP.

The pad for mounting the pump is detachable and may be located in any one of three positions at 90 deg. to each other. It is fastened by two flush-head screws.

As regularly furnished with ¾-in. pipe, the pump has a capacity of 15 gal. per minute with a 15-in. suction lift against a 4-ft. head at a pulley speed of 450 r.p.m. When equipped with 1-in. piping the discharge can be easily increased. Variation of the pulley speed naturally varies the output of the pump.

ORGANIZING TO BRING NIAGARA PENINSULA TO ATTENTION OF WORLD

THE municipalities of the Niagara district have organized the Niagara District Industrial Association, with the object of holding, during the present year, an industrial congress. By this means they will endeavor to attract responsible people who may be interested in the power shipping and industrial facilities of the district, and also in the fruit and farm areas. Plans will be made to have their guests visit the power development at Niagara Falls, the Chippawa Power Development, now under way; the Welland Canal enlargement, and the fruit belt. Literature will be prepared describing these outstanding features of the district, and each municipality will also give wide publication to its advantages from an industrial viewpoint. Lists of representative men will be prepared, with the object of inviting them to the congress as the guests of the association.

The officers are:—

President, W. M. German, K.C., Welland.

1st vice-president, H. P. Stephens, Mayor Niagara Falls.

2nd vice-president, E. J. Lovelace, Mayor St. Catharines.

3rd vice-president, George W. Sutherland, Mayor Welland.

Secretary, Louis Blake Duff, Welland.

Treasurer, E. C. Graves, St. Catharines.

Publicity Committee:—W. B. Burgoyne, St. Catharines; F. H. Leslie, Niagara Falls; J. H. Thompson and J. E. Carpenter, Thorold; B. J. McCormick, Welland; P. B. Yates, St. Catharines; H. W. Shore, Port Colborne.

The members of the association are the representatives of the municipal councils of :—

(a) St. Catharines, Niagara Falls, Welland.

(b) Thorold, Merritton, Port Colborne, Bridgeburg, Niagara-on-the-Lake.

(c) Port Dalhousie, Fort Erie, Hubberstone Village, Chippawa.

(d) Crowland, Thorold Tp., Stamford, Bertie, Grantham, Niagara, Louth.

The representatives of the following Trade Boards:

(a) The Niagara Falls Chamber of Commerce.

(b) The St. Catharines, Merritton, Thorold, Welland, Port Colborne, Ridgeway, Fort Erie, Port Robinson and Stamford Boards of Trade.

TRADE OPPORTUNITY IN CUBA

The old-established British firm of Albert Moloney and Co., 12 Amargura St., Havana, Cuba, is anxious to obtain sole agencies in Cuba for the following heavy machinery manufactured in Canada: Return tubular boilers, water-tube boilers, condensers, surface, jet, and barometric, power pumps of all types, steam driven, motor and belted, vacuum pumps, steam engines, valves and fittings, electrical generators and motors.

Canadian manufacturers might bear in mind that Americans enjoy a preferential tariff in Cuba, but that this is more than offset at the present time by the discount on the Canadian dollar. Another substantial assistance to Canadian trade with Cuba is the recent establishment of a direct line of the Canadian Government Merchant Marine between Canadian ports and Havana.

At a recent meeting of the Montreal branch of the Engineering Institute of Canada, an address, illustrated by motion pictures, was given by John Murphy, M.E.I.C., electrical engineer of the Department of Railways and Canals, Ottawa. The subject, "Ice Formation," was ably dealt with by the speaker, and the pictures showed the audience the actual formation of frazil and anchor ice and the manner in which submerged machinery at temperatures below the freezing point attracted the spicules of ice and invited disaster to the equipment.

W. H. Rose, formerly with G. W. Cole, Ltd., has been appointed general manager of the Canadian Farnsworth Company. This company has been organized in Canada to operate the Farnsworth Canadian patents. Active manufacturing has been started in their plant on Hillington Ave., Toronto. The Farnsworth patents cover duplex automatic boiler feeders, condensation pumps and return steam traps.

The Operators' Point of View

Correspondence Re Graded Certificates

A CONCRETE SUGGESTION FOR IMPROVEMENT

The Editor:—Your editorial on page 70, THE POWER HOUSE, noted. The new license law has many good points. Any man who does not understand the technical or theoretical side of engineering is not an engineer, he is simply a laborer, what is called a "wop." However, there is a limit to everything and it is quite possible to go beyond the proper limit in technical requirements to secure a license to operate power plants, although it is not possible that any one man can have too much technical knowledge.

Personally I believe that the size of the power plant operated by second and third class license holders should be larger than the new law allows, 300 B.H.P. for the third class and 800 B.H.P. plans for the second class men would be about right.

This would allow the men of ordinary intelligence and experience to earn a fair living. Under the present law, it appears to the writer that only the exceptionally clever man can pass a highly technical examination if he is not allowed to use books of reference. I have had brought to my notice many illustrations of the foregoing fact. The late Mr. M. L. Smith, ex-associate editor of THE POWER HOUSE, and engineering instructor at the Toronto Technical School, was a personal friend of mine. Several times Mr. Smith asked me for answers to some practical power plant problem which was bothering him. He was a technical expert of high ability, but he informed me that often he would be engaged until midnight, and later, searching through textbooks to find the answer to some question asked by a reader. When I attended the meetings of the C.A.S.E. in Toronto, some years ago, I have seen question slips brought out which none of the members could give detailed answers to from memory. Engineers all over the province of Ontario are delighted to have a graded license law, but from my conversations with different men the one big kick seems to be dissatisfaction with the smallness of the plants allotted to the second and third grade license holders. Like myself the majority of the engineers I have talked to are positive they can not pass a highly technical examination from memory, even when they are, like myself again, graduates of the I.C.S. or A.C.S. holding their engineering disploma. It would be quite all right to leave the first class examination as it is, then the exceptionally clever men could have the high class, big paying positions, which is only right and proper. If this is so, the other fellows, who are only moderately clever, or simply first class mechanics and second class engineers and technical men, should be allowed the priviledge of earning a fair living in a moderate sized power plant.

I believe if the change suggested in this letter were put through, there would be little or no objection to leaving the act as it is written.

JAMES E. NOBLE,
First Engineer,
Ontario Hospital,
Kingston, Ont.

ANOTHER GOOD SUGGESTION

It has been with much interest I have read the correspondence on this subject, and when Chief, Justice I, II, and An Old Engineer, get their first-class certificate (which I have not the least doubt they eventually will), I wish they would tell us about it.

But in the meantime I would like to put another phase of the subject on record. Those holding second and third papers and wishing, by study and labor to advance themselves in their positions, deserve some consideration.

Mr. D. F. Campbell promises to help. Arthur Smith offers a solution to the problem, but could the average engineer give the correct answer to the formula.

When I say average I mean 50 per cent. of the engineers. When I obtained my certificate I had to prove that I knew my business, but I saw nothing of square roots.

I have a good library on engineering subjects by several authors, but in many things, particularly mathematics, I find the rules are not given clearly, and it is often necessary to check one book against another.

I would suggest that all readers who are interested in their own advancement ask POWER HOUSE to give one page (or more if it is possible) to help those who would help themselves.

In the December 20, 1919 issue we had a clear and concise explanation of several rules of mathematics. I would suggest a portion of the space to mathematics, chiefly because they are so necessary for all other problems—the balance to electricity, air, water, refrigeration, usages, breakdowns, repairs, etc.

Also a department where anyone, wishing to obtain advice on technical books, libraries, and courses, could do so. I for one am glad of the graded certificate; it will mean study for many, but good for the largest number.

I hope I have started the ball rolling another way, and hope to hear more good-natured grumbling.

A. O. STONE.

Editor's Note.—The suggestion contained in the above letter quite meets with the approval of the editors, and we are glad indeed to devote whatever space is necessary to these subjects. In fact a rather extensive series of educational articles is in the course of preparation, and in addition we would request the cooperation of our readers to the extent of their sending in concrete suggestions, especially questions concerning any particular portion of engineering, theory or practice, which may not be clear to them. Questions actually sent in by readers are of more value than those otherwise prepared, since they are apt to come more closely to the engineers own requirements.

A Letter from Justice the Second

The Editor:—"Chief," in replying to my letter of December 5th, which appeared in your issue of that date, states that his plea was and is for the man who, by perseverance and determination based on an ambition that any man should be proud of, have overcome all obstacles and attained a position in charge of a large plant. He then goes on to state that he has a very intelligent engineer in mind, one who is in charge of a large plant, but yet could not even pass a second-class examination, is having very good results from his plant. How can this be possible? Is it not the case that to be an economical operator, one must have a fairly good theoretical

understanding of engineering? And this combined with his practical knowledge should produce efficiency. If "Chief" can prove to me that economy and efficiency of a power plant can be got otherwise, I will be more than obliged to him for the formulae, thus saving me further time and study of engineering books.

Yes, we all know that the much-coveted paper will not make the man but now that "Chief" as one of the agitators of graded certificates has persuaded the Government of Ontario to adopt same, surely he thought that the paper would be of some benefit to the engineer of to-day and more especially of to-morrow. If that be the case, what other fair and square means can be adopted but by the examining of each and every individual engineer to test his true knowledge of the questions that shall be of a highly practical and theoretical nature as the small handbook issued on the subject of graded certificates by the Stationary Engineers' Board hath set forth.

Perhaps it may be of interest to "Chief" that very recently an important position was to be filled by an engineer, and after being duly advertised some 60 applicants entered the field for same. It was no simple matter to discriminate the winner, as all had first-class references and knew engineering from A to Z. A test examination was to be the deciding factor, then, alas what happened? Seven out of the sixty appeared for examination and only five attempted it. Doubtful if any ever reached the goal. Approximately 90 per cent. of the highly referable applicants' bluff was called.

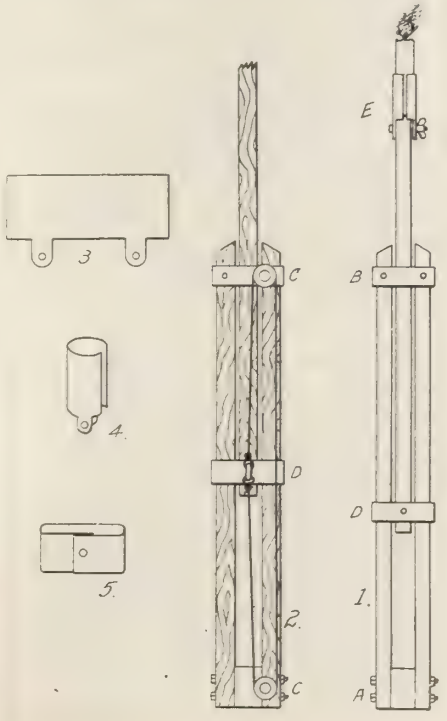
Will the grading of certificates not place the majority of the self-estimated, first-class, economical and efficient chief engineers of to-day in such a position?

JUSTICE II.

TELESCOPIC CANDLESTICK

By J. O. McDONNELL

The accompanying sketch shows a telescopic device for carrying a torch or candle for use in the boiler room where it is frequently necessary to examine the inside of the boiler when cleaning, or in such places about the boiler room where it would be very difficult to reach without an apparatus of this description. It is sometimes the practice to use a long pole for this purpose but this method is often awkard owing to the confined space available. The simple and cheap extension here shown can be made in a very short time by any handy man about the plant and adjusted to any desired length to suit the working conditions. The use of such a device will often save the crawling into difficult and dirty places for inspecting and repairing. The frame is constructed of light strips of wood about ¾ inch square and of a length suitable to the class of work for which it is to be used. The base is secured by a small block of wood bolted by a small block of wood by a couple of small bolts as shown at A. The upper end is fastened as shown at B with a short piece of band iron. The centre extension piece is also made of a strip of wood ¾ inch square with a clamp secured to the bottom that keeps it in place while in use permitting of free movement when travelling along the supporting frame. When an extremely long extension is required it is advisable to use a cord that passes around two pulleys, one at the base and the other at the top of the frame, the ends of the cord being secured to the clamp that is fastened to the bottom of the movable centre piece. The holder for the candle which is fastened to the top end of the centre piece, is made of a small piece of tin of a shape shown in Fig. 3, and bent into the shape shown at Fig. 4. The candle holder is so made that the candle may be placed in any desired position by swinging on the small swivel bolt that holds it to the stick. Fig. 5 is a view of the clamp that is fastened to the base of the centre stick. The cord and pulley is not always necessary but is very convenient when a long extension is required.



THE NEEDS OF PRACTICE

There is one feature which is common to all the infinite varieties of mechanism with which the engineer has to deal—namely, the necessity for lubrication. Yet, in spite of the fundamental importance of the subject, the principles of lubrication have, until recently, received but scanty attention at the hands of scientific men.

It is true that Beauchamp Tower studied the action of oil in a bearing and Osborne Reynolds developed a mathematical theory based upon his experimental results, but it is not derogatory to the work of these and other investigators to say that the present state of the art of lubrication is far in advance of any scientific theory. The engineer has found out by experiment what kinds of oil or other lubricant give the best results under various conditions of use, and in what circumstances satisfactory lubrication is possible; yet as to what constitute the determining factors in these cases he is almost entirely in the dark. Enlightenment as to the nature of these factors is required not merely for intellectual gratification, but for the severely practical purpose of improving our machinery. If we knew upon what lubrication ultimately depends and understood the molecular mechanism by which it is accomplished, it might be possible to devise lubricants or bearing surfaces which would permit of vastly greater working pressures than are now permissible, with a consequent revolution in the design of machinery. A wide and almost untouched field of research lies open to the physicist and the chemist, the exploration of which would benefit the engineer in a very direct and practical manner. The work has been taken up by the Research Committee on Lubrication, and it is sincerely to be hoped that the outcome of their labors will be to place the whole matter upon the scientific basis which its importance deserves.

Function of a Lubricant

The primary function of a lubricant is to make surfaces slippery, so that they may slide over each other with the least amount of frictional resistance. The usual lubricants are, of course, oils of various kinds, and Mr. R. M. Deeley, in a communication read at a recent meeting of the Physical Society, refers to the specific property of liquids, in virtue of which they reduce friction as "oiliness." This hardly seems more illuminating than the definition of an archdeacon as a man who exercises "archdeaconal functions." Moreover it appears either to beg the question or to be misleading. For example, one of the slipperiest substances known, and one which is always associated with ease of sliding, is ice. It is generally assumed that the "lubrication" which makes ice so slippery is a minute film of water caused by the momentary liquefaction of the ice under the pressure of the sliding body. At any rate, whether this is so or not, there is nothing about the phenomenon which would justify such a word as "oiliness" being used in connection with it. Water is said also to make a good lubricant for surfaces of ebonite, and it serves to lubricate the sterntubes of steamships. It is, however, quite inadequate for ordinary metallic surfaces for which universal experience indicates some sort of oil or grease to be the only practical lubricant.

Why oils possess the property of lubrication in so marked a degree, as compared with other liquids, is something about which we are still awaiting an explanation from the physicist. Moreover, oils which are for all practical purposes identical in viscosity and other characteristics prove to be of very varying merit as lubricants. It has been suggested that to be a good lubricant, any oil, whether of organic or mineral

origin, must contain a number of unsaturated molecules which attach themselves to the metallic surfaces by their residual affinities. Thus the interface between the solid metal and the oil film is looked upon as being composed of a sort of alloy or amalgam of oil and metal, which prevents the oil film from being rubbed away. The necessity for unsaturated molecules is, however, denied by other authorities, and there the matter rests. What does seem to be certain is that good lubricants appear to have the power of attaching themselves strongly to the rubbing surfaces, and of retaining their adhesion under very considerable shear stresses.

What the Engineer Wants to Know

The engineer is quite content to wait until the physicist and chemist have come to some agreement with regard to the molecular explanation of lubrication, but he is pressing them for some practical guidance which will help him to decide upon the suitability of an untried sample of oil for some particular purpose. To make an actual test of a new kind of oil upon an important machine, such as a large gas engine or turbine, is an expensive matter, and is not without a certain risk of injury to the machine. The engineer consequently is tempted to bear those ills he has rather than to risk incurring others that he knows not of, and he therefore often continues to use a high-priced oil for fear of experimenting with a cheaper one. To add to his difficulties the salesman of the new oil may claim that it is identical in character with that which he desires to supplant, and may point to the fact that as regards viscosity, flash point, fire point, and other features the two oils are indistinguishable. Every engineer who has purchased oil on a large scale must have had experience of this kind, and many a one has found that the cheaper substitute fails in just the feature which is essential—namely, the power to lubricate efficiently.

When oil has to be purchased by tender this ignorance of the factor upon which lubricating power depends is a serious matter. The buyer cannot protect himself by requiring bidders to conform to any specification, however rigid, because in the present state of our knowledge it does not appear to be possible to draw up a specification which will ensure that every oil which conforms with it shall be a good lubricating oil. In more than one case an oil company has been asked to furnish a specification of some of its oils which have proved satisfactory, the specification to be so rigid that none but oils absolutely identical with its own could satisfy it. In spite of a promise to the company that tenders would be called on such a specification, thus practically throwing a valuable contract directly into its hands, the specification was never forthcoming. It appears that all the engineer can do at present to ensure uniformity of quality of his lubricating oil is to purchase some brand under a trade name, and trust to the honesty of the sellers that the name shall always connote the same quality. This is unsatisfactory in the last degree, and matters cannot be improved until those who preach to him the duty of conducting his business along scientific lines will furnish him with specifications and methods of testing which will place the purchasing of oil on a more scientific footing.

Oil-Testing Machines

There have been on the market for many years various machines designed to test the lubricating qualities of oil under conditions comparable with those under which it is to be used. In the more elaborate of the machines tests may be made of the friction occurring at various speeds, temperatures, and pressures, and autographic records may be obtained of the variation of friction with time. These testing machines do not, however, command the general confidence of engineers as a guide to the merits of an oil. None of them, so far as we know, can provide conditions even approximately resembling those which obtain in a gas engine cylinder, steam cylinder, or turbine bearing. Moreover, the results obtained by different machines are not comparable, so that oil cannot be bought on the guarantee that it will give certain results in a testing machine. The utility of the machines really consists in enabling the engineer to test different samples of oil for similarity of behaviour under similar conditions, or to compare periodical tests of the same brand of oil with one another. They have a certain scope for these purposes, but the relationship between the figure of merit they would award any particular oil and its real merit in practical use is by no means definite.

What an engineer usually wants to find out is whether a new sample of oil offered him is better or worse than that which he is using. There would, therefore, seem to be room for a simple machine which would indicate the differential friction between two similar pairs of surfaces working at precisely the same pressure and temperature, and lubricated, one with the sample of oil to be tested and the other with the oil in ordinary use. It is true that it would not be possible to imitate the actual factors which influence the life of an oil, such as the presence of steam or flaming gas, but nevertheless the ease of making a simultaneous comparative test of two oils under necessarily identical conditions would be worth something.

Work Waiting to be Done

Without minimizing for a moment the scientific interest, and no doubt also the ultimate practical use of the investigations now being carried out by the Committee on Lubrication, as to the real explanation of lubrication, it may be suggested that work of a more immediately useful nature lies ready to their hand. If, without interrupting the researches they are now making into the physical basis of lubrication generally, they could spare the time to draw up specifications for oils suitable for certain difficult conditions, they would confer an immediate benefit upon engineers. In the case of the lubrication of the cylinders and glands of large

To The Stationary Engineer

A number of engineering correspondents have written us respecting various phases of the Graded Certificate Act now in force in Ontario. Many of these letters have been more or less severe in their criticism of the Act, and while the pointing out of defects, real or fancied, is important and of value towards their betterment, little has been given in the way of constructive criticism.

No one is better able than the engineer himself to give suggestions as to improvements to be effected either in the Act or in the Regulations under which it will be carried out, and since each engineer has, or should have by this time, his copy of the Act and its Regulations, he should be in a good position to form his own opinions. Not only so, every engineer has no doubt given the matter considerable thought, and, having read both the Act and Regulations carefully, has his own ideas as to both, and can suggest improvements.

We are, then, asking that the stationary engineer send us a letter in which improvements and suggestions are embodied. No matter what your opinions are, send them in for publication and discussion. The requirements for examination, the type of questions which you think should be asked, the length of service, the size of plants for each certificate, and similar matters are all suitable subjects for discussion.

It is only by free discussion that any legitimate change can ever be brought about, and the columns of POWER HOUSE offer an ideal medium for the freest discussion, leading eventually to a crystallization of the general thought of the engineers of the Province.

One thing more, and equally important—the education of the engineer should be an important feature of the educational system of Ontario. The Department of Education has taken a long step forward by establishing night classes for the engineer throughout the Province. Since these have only been functioning since the late fall, in most cases, it is possible that the subjects taught might not be just what you require, or the courses in other ways could be bettered. Let us have your thoughts regarding this, and send in your suggestions as to what you would like to see taught, and how.

double-acting gas engines, for example, the Committee might obtain samples of the oils used in various plants with success, and from the practical knowledge so acquired draw up specifications defining the kinds of oil most suitable for various conditions of temperature, pressure, and rubbing speed. In this instance, of course, the tendency of certain oils to form hard carbon deposits in the glands and cylinder heads is a point which has to be noted. Should the Committee not be able to draw up any specification of practical use, possibly they could indicate simple tests, chemical or mechanical, which would serve to differentiate good from bad oils. Again, a standard specification for turbine oils suitable for various conditions would be useful. A note as to the permissible rise of temperature without risk of injury to the oil, the question of the "life" of a turbine oil, and the conditions which render an oil useless on account of what has been explained as polymerization, are all subjects on which guidance might be looked for from the Committee.—Engineering Supplement the London Times.

CARBON DIOXIDE RECORDERS

Continued from page 91

more than five or six per cent. of carbon dioxide in the flue gases, although until the test was made there was no suspicion that anything needed improvement. By careful attention to the settings, the grates and the method of firing, this can always be raised to an average of 12 per cent., and even 15 per cent. can be reached, although this is about the practical limit, having regard to the necessity of avoiding the production of carbon monoxide. To show the importance of proper attention to the dioxide percentage, we will suppose that the introduction of a recorder has resulted in the average percentage of that gas being raised from 5 to 12 per cent., and we calculate the saving resulting from the change. It has been mentioned that if perfect combustion could be obtained with no excess of air, the proportion of dioxide in the flue gases would be about 18 per cent. The quantity of air necessary to give this result would be about 144.5 cu. ft. per lb. of coal, supposing the latter to contain 87 per cent. of carbon and five per cent. of hydrogen. If, therefore, the percentage of dioxide were reduced from 18 to 5 by the dilution of the flue gases with air, it is clear that the total volume of air passing through the furnace would be $(144.5 \times 18) \div 5 =$ 520 cu. ft. per lb. of coal burnt. The excess air is therefore $(520 - 144.5) =$ 375.5 cu. ft. per lb. coal, and supposing the flue gases to leave the boiler at a temperature of 500 deg. Fahr., this excess air will carry away about 3,000 B.t.u. to waste, or more than 20 per cent. of the heat of the coal.

A similar calculation shows that if the dioxide in the flue gases amounted to 12 per cent. the excess air would be 72.25 cu. ft. per lb. of coal. This quantity of air would carry away nearly 600 B. Th. U., or less than 4 per cent. of the heat of the fuel. The effect, therefore, of increasing the percentage of dioxide from 5 to 12 would be to effect a direct saving of something like 16 per cent. of the fuel. This is a saving quite within the reach of hundreds of plants throughout the country, and apart from the national importance of conserving our fuel supplies, it is a material consideration with the present price of fuel. Many an engineer regards the low flue-gas temperatures which he is getting as a proof of the efficiency of his boiler-plant, whereas if the temperature is low merely on account of the furnaces and settings being flooded with cold air entering where it should not, he is living in a fool's paradise.

Choice of an Instrument

With so many thoroughly serviceable types of automatic recorders on the market, it would be invidious to recommend any particular design. The engineer, however, may be counselled to select a thoroughly simple and mechanical type, and particularly one which can easily be taken apart and cleaned when necessary. The first cost of any of the commercial types is inconsiderable in comparison with the savings resulting from attention to their indications, so that the choice should be determined more by the mechanical qualities of the instrument and its suitability to boiler-house conditions than by its price. Furthermore when instruments have been installed, it is worse than folly to neglect them, as soon as their novelty has worn off, because of the very slight amount of attention required to maintain them in efficient working condition. One is sometimes tempted to think that it is not their trouble which is the real reason for their neglect, but rather the fact that their records are inexorable witnesses to conditions of inefficiency which otherwise would pass unnoticed. —"Times Engineering Supplement."

PRODUCTION OF ASBESTOS INCREASING

The asbestos industry of the United States is in better condition now than ever before, especially as to the quantity and the grade produced, and the outlook is encouraging. Most of the asbestos used in the large asbestos factories of the United States comes from Canada, but the growing appreciation of the high quality American fiber, especially that from Arizona, is a welcome feature of the industry.

The total quantity of domestic asbestos sold in 1917, according to J. S. Diller, of the United States Geological Survey, Department of the Interior, was 1,683 short tons, valued at $506,056, an increase of about 13 per cent. in both quantity and value over 1916. Most of the domestic asbestos comes from Arizona, where the proportion of crude spinning fiber to that of lower grades is much larger than in Canada, so that the average price of American fiber in 1917 was $301 a ton, whereas the average price of that in Canada was only about $50.

Some years ago the opinion was expressed that as the Arizona fiber contains less iron than that mined in Canada, it is therefore better adapted to use for electrical insulation than the Canadian fiber. This opinion has lately been confirmed by analyses made by R. E. Zimmerman, of Pittsburgh, whose investigations also indicate that the harshness of certain parts of the Arizona asbestos is due to thin films of calcite among the fibers.

A small amount of spinning fiber was mined in Fremont County, Wyoming, from a contact deposit of remarkable interest.

The increased demands for asbestos due to the war have been met largely by increased imports from Canada. The imports of asbestos from South Africa and Italy have been largely cut off. The demand for imported asbestos for use in filters is being supplied by amphibole asbestos obtained from residual deposits of the crystalline rocks of Maryland.

TENDERS

The city of Brantford requires tenders for cement, sewer pipe and crushed stone. Tenders addressed to Ald. Harry Simpson, chairman of the Board of Works, will be received until Feb. 19. Specifications may be obtained from the city engineer, T. Harry Jones.

The secretary of the town of Ingersoll will receive tenders until February 28 for the erection and completion of a sixteen-room public school, of tile and concrete construction, fireproof. Plans can be obtained from the architect's office.

The Lignite Utilization Board, 2 Youville Square, Montreal, are calling for sealed tenders for the supply of material and erection of buildings at the plant in Estevan, Sask. The work includes the construction of industrial buildings and a concrete reservoir, and the erection of a water tank on a 70-foot tower. Complete plans and specifications can be obtained from the Board's offices in Montreal, or at the office of Mr. J. M. Leamy, Power Commissioner of the Province of Manitoba, Winnipeg. Tenders must be in by March 6.

The Department of Public Highways are calling for tenders for the supply of and erecting field painting of the steel superstructure for a 170-foot steel bridge over the River Aux Raisin in the vicinity of Lancaster. Plans and specifications can be obtained from the office of the Resident Engineer, Cornwall, and at the Department, Toronto. Tenders will be received till March 9, 1920.

To Manufacture Oxygen.—The Dominion Oxygen Co., a subsidiary of the Union Carbide and Carbon Corporation has been organized and will build five plants in the Dominion. Toronto will have one of these plants, and there will be in addition service stations and warehouses for supplying the small cities. The headquarters of the new company will be in Toronto, and work will be started almost immediately.

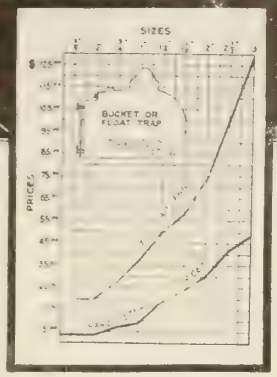
See What You Save on Steam trap SARCO



This diagram shows at a glance the big difference between the size and the price of the clumsy, cumbersome bucket trap and the simple, compact Steam Trap SARCO.

The difference in size and the difference in price are, as a matter of fact, cause and effect. For it is the larger size of the bucket trap—with its extra superfluous parts such as floats, levers, valves, water gauges, bowls, toggles and packing—that you have to pay the larger price for. It is the compactness and simplicity of Steam Trap Sarco that makes it possible for you to buy it for one-third the price of the bucket trap.

Rated size for size, Sarco has the same capacity as the big float trap. Its efficiency is greater. It discharges condensate as rapidly as it collects, consequently doesn't need to be large. It closes promptly and prevents all loss of live steam. Its compactness permits it to be installed in many places where there would not be room for a cumbersome bucket trap.

Why, therefore, pay the **larger price** for a bucket trap when it gets you neither increased capacity nor increased efficiency?

Use Steam Trap Sarco and save two-thirds of your Steam Trap Costs. Will send it on thirty days' free trial and let it convince you in your own plant, away from the influence of salesmen, that the Sarco is all we claim, and more.

TRADE GOSSIP

Engineers' Club Closes Year.—The Engineers' Club of Toronto has just completed its 20th year, which has been the most successful in its history. Owing to the fact that their premises are not capable of accommodating any large number of new members, it was decided to raise the entrance fee 100 per cent.

New Brantford Industry.—S. C. Johnson & Co., of Racine, Wis., have purchased a portion of the Waterworks property in the neighborhood of the Robbins & Myers plant. The firm are manufacturers of prepared wax and wood stains, and they will erect a factory early this spring and employ 100 hands before the end of the year.

The Oil Engine Works of Canada, operating for the past few months at 29 Prince Street, Montreal, will shortly move their plant to Iberville, Quebec, taking over a portion of the plant now occupied by the Rapid Tool and Machine Company. They are building the Hvid line of oil engine in 6 and 8 h.p., principally for the farm trade. M. L. G. Vincent is the managing director.

Canadian Nathan Co. for Hamilton.—The Canadian Nathan Co., which will be closely allied to the Nathan Manufacturing Co., of New York, will shortly be established in Hamilton. The new company has arranged to take over the plant of the Canadian Chadwick Metal Co., and the premises will be remodelled and fitted with the necessary machinery to manufacture the Nathan line of valves, injectors, lubricators, etc.

N. B. Timber Transaction—The lumber lands and two mills on the Tobique river, owned by the Upham Lumber Co., Ltd., have been sold to the Fraser Companies, Ltd., for a sum reported to be $100,000. The purchasers will take this season's cut of six million feet. The principal stockholder in the Upham Company is George W. Upham, ex-M.L.A., of Woodstock, and the stock is held entirely in his family.

Dominion Foundries Extends.—The mills of the Dominion Foundries at Hamilton are undergoing large extensions, the cost of which will be in the neighborhood of $1,000,000. The plate mill is expected to be put in operation within the next two months. There are orders on hand for plates enough to keep the new mill busy for the rest of this year and well into next. All the other departments are booked up for some time.

T. W. Rogers has joined the staff of the St. Lawrence Welding Company of Montreal, and will have the position of general sales manager of the company. Prior to his recent appointment Mr. Rogers was eight years with Darling Bros., four years as a travelling salesman and the last four as purchasing agent. He was formerly with the heating division of Taylor Forbes Co. The tank development of the St. Lawrence Welding Company will necessitate additional selling organization and Mr. Rogers will have full charge of this department.

New Company in Welland.—The Marvel Company of Welland has been incorporated and will carry on the business of manufacturing and dealing in automobiles and accessories of every description. They will manufacture the "Marvel" steering device for Ford cars and deal in light, heat and power.

Briquette Plant Being Pushed.—The briquette manufacturing plant which is being constructed by the Lignite Utilization Board of Canada, at Bienfait, Sask., will be actively proceeded with as soon as the season opens. Some of the machinery contracts have already been let. The capacity of the plant will be 30,000 tons per annum, and production should start in August next.

The Annual Refrigeration Number of Power House

will be issued on April 20th. This issue presents a splendid opportunity for advertisers of ice and refrigeration equipment to bring their name and lines favorably before the Canadian trade.

Arrange Now for Special Advertising in the REFRIGERATION NUMBER

OPPORTUNITIES

SEALED tenders will be received up to and including March 1st, 1920, to cover the installation of a distribution system of electric lighting in the town of Capreol, Ontario. Plan and specifications on request.

W. H. MATHEWS,
Town Clerk.

STATIONARY ENGINEERS

Those who wish some practical tuition for their Graded Certificates from a practical power house engineer holding highest certificates are invited to communicate with T.H.F., Box 208, Power House.

Stopping an ad to save
money is like stopping
a clock to save time

Where Do You Live?

We are going to put a representative in every town in Canada. Be the one in your territory.

We teach you how to build a permanent, substantial business. Whole or spare time. Write for particulars to-day.

Dept. B., Agency Division
153 University Ave., Toronto, Ont.

LIKE EATING, ADVERTISING SHOULD BE CONTINUOUS. WHEN TO-DAY'S BREAKFAST WILL ANSWER FOR TOMORROW'S YOU CAN ADVERTISE ON THE SAME PRINCIPLE.

Manager wanted, for Canadian National Newspapers & Periodicals Association. To act also as Secretary-Treasurer, and carry on the Association's general work, under the direction of the President and the Board of Directors, study the interests of the various classes of publications in the Association, and plan and carry on promotion work in their interests. Applicants should understand advertising and merchandising. Apply in writing only, stating age, full details of experience, and salary expected. Applications will be treated as confidential. Address Acton Burrows, President, Canadian National Newspapers & Periodicals Association, 70 Bond Street, Toronto.

Instructive Advertisements

"I think the advertisements are good and I read them all the time. If it was not for the ads. an engineer would not be able to keep up-to-date on new eqiupment. It is the only way we learn about anything new, as circulars are mostly kept in the offices," writes a Hamilton reader.

Double Moral—Read the Advertisements. Use Power House for Advertising.

SPLENDID OPPORTUNITY

Engineer or **Steam Specialty Salesman wanted** to handle a high grade Canadian-made return steam trap. District, Quebec. Headquarters, Montreal. A good proposition to the right man. All inquiries confidential.

Apply to Box 210,
POWER HOUSE

The advertiser would like to know where you saw his ad.---tell him.

The Growth of the Deadly Drug Habit

IN the year 1912 only 35 ounces of Cocoaine was imported into Canada. Last year the imports had jumped to 12,333 ounces. In 1907 Canadians imported 1,523 ounces of Morphine. Last year we imported 30,000 ounces.

These figures tell a grim story. The drug habit is growing in Canada—growing so fast that it has become a national menace. The war, by teaching the use of opiates, has stimulated the habit and to-day the insidious disease is creeping into our homes and spreading its coils around countless victims. No class is exempt. It strikes everywhere.

Mrs. Murphy (Janey Canuck), police magistrate of Edmonton, has been engaged by MACLEAN'S MAGAZINE to write a series of articles on the danger and the means of checking it. The first article of this series appears in the February 15th issue (now on sale) and it is a powerful appeal for action against "the human canker-worms and caterpillars who fatten and batten on the unfortunate drug addicts"—the men and women who smuggle and sell the drugs. No better person could have been secured to handle this subject, for Mrs. Murphy is not only a powerful writer, but in her official capacity she has had an opportunity to see all phases of the drug traffic. What she writes has the ring of absolute authority.

Other Readable Features of a Strong Number

This, the first number of MACLEAN'S to appear on the semi-monthly basis, is a particularly interesting one. Here are some of the features:—

THE STORY OF THE ALLENS
By Floyd S. Chalmers

How Jule and Jay J. Allen built up their business from a two-by-four theatorium in Brantford, Ontario, to a twenty million dollar string of theatres—the story, in fact, of a business miracle.

THE BLOOD BROTHER
By W. A. Fraser

A strong, short story by the author of "Bulldog Carney" and "Thorobreds."

THE LAND OF NANNABIJOU
By Charles Christopher Jenkins

There's a huge part of Canada that has tremendous possibilities and yet has been neglected, overlooked. Mr. Jenkins tells about it.

THE MANTLE OF ELIJAH
By J. L. Rutledge

An unusual sketch of a politician, Ernest Lapointe, who is regarded as the successor of Laurier as leader of the Quebec wing of the Liberal party—a fascinating bit of inside political gossip.

THE DIAMOND HUNTERS
By Henry P. Holt

An exciting story of two Canadian sailors in the South Seas.

THE THREAD OF FLAME
By Basil King

A powerful serial story by this famous Canadian author.

And a score of other features—stories, articles and reviews.

Over 80,000 Canadian Families Read

Jenkins Bros. Valves

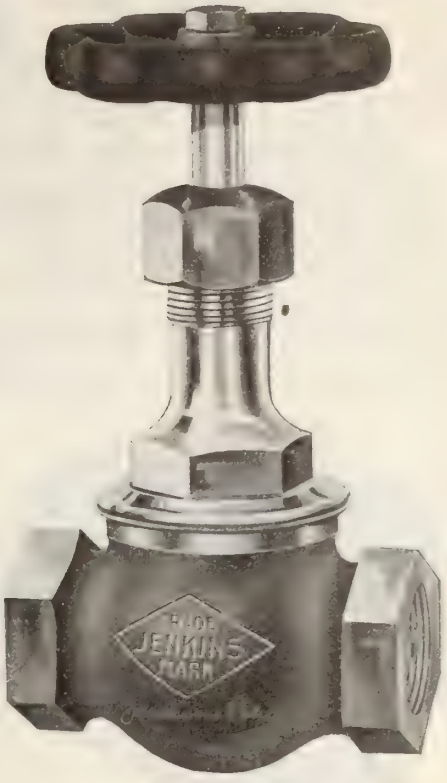

Fig. 106

JENKINS' Valves are recognized as the Standard in all parts of the World and wherever there are supply houses—Jenkins' Valves will be found. The standard of quality never changes except to improve, and while to-day there are hundreds of imitators, the sales of genuine Jenkins' Valves are constantly increasing.

A Fair Offer

If you will put a Jenkins' Valve on the worst place you can find, where you cannot keep other valves tight, and if it is not perfectly tight or does not hold steam, oils, acids, water or other fluids longer than any other Valve—

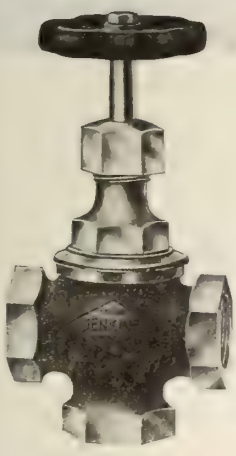

Fig. 110

YOU MAY RETURN IT AND YOUR MONEY WILL BE REFUNDED.

For Every Purpose

There's a Jenkins' Valve for every purpose. You will know the genuine by the Diamond Trade-Mark with the signature Jenkins Bros., cast on the body. Never fail to look for it. It means service and economy to you.

Jenkins' Valves are approved by Department of Public Works in Ontario and Western Provinces. Stocked by first-class dealers everywhere. Catalogue No. 8 free on request.

Protect your small motors with——

CONDIT

Type I Oil Starters

Safety

All mechanism and live parts are entirely enclosed — fuses are dead when switch is in open position — may be locked in open position. This means absolute safety.

Motor Protection

Starters are of **Oil switch construction,** equipped with enclosed fuses for overload and short circuit protection.

Special design enables fuses of approximately full load running current to be used, **which will not blow during starting period.**

It is equipped with low voltage release which immediately disconnects the motor on power interruption or any considerable drop in voltage.

Handle cannot be left in starting position.

Installation and Maintenance

The Conduit Type I Motor Starter is compact and easily mounted on any flat surface.

It is equipped with interchangeable knock-out plates arranged to receive 1½", 1", ¾" or ½" Conduit.

Both movable and stationary members are identical, interchangeable and reversible, reducing maintenance work to a minimum.

The liberal design of conducting parts insures long life.

Ample space in the case for making connections.

Our nearest house can supply you.

Deputy Minister:
W. A. Riddell, Ph.D.

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a STATIONARY steam plant of 60 B.H.P. or over, in the Province of Ontario, must hold a Stationary Engineer's certificate from the Board of Stationary & Hoisting Engineers. Anyone operating such a plant without a certificate is liable to the penalties set forth in the Act respecting Stationary and Hoisting Engineers.

After January 1st, 1920, the Certificate issued by the Board will be of four grades, viz., First, Second, Third, and Fourth. Application forms for graded certificates will be mailed upon request after the above-mentioned date. The certificates now issued by the Board will be graded into Third and Second-Class upon renewal, same being classified from the information contained in the renewal application which will be sent to each certificate holder.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse-power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating **such a plant without a certificate is liable** to the penalties set forth in the Act respecting Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1st, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request. The B.H.P. and other information contained in these forms is to be used for statistical purposes. A Registration Certificate will be issued to each applicant. All applications, or requests for same, should be mailed to the Chairman.

W. C. MCGHIE, CHAIRMAN OF BOARD

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

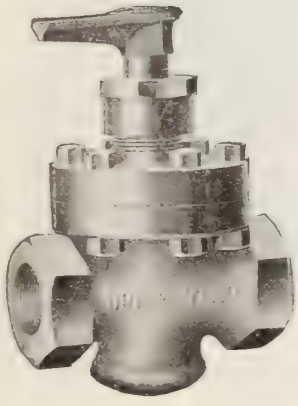
All steam boilers built in, or entering the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., c. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, Parliament Buildings, Toronto.

D. M. MEDCALF, CHIEF INSPECTOR OF STEAM BOILERS

HOMESTEAD
Quarter-Turn Valves



Give Better Service Than Globes and Gates

Homestead Valves provide full pipe area and give straightway, unobstructed flow.

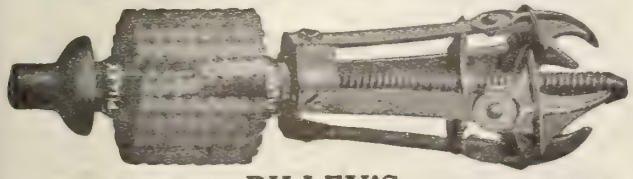
A quarter-turn opens a Homestead Valve — a quarter-turn closes it. Adopt the Homestead in place of your globe and gate valves; better service is assured.

Used for every service —air, steam, oil, water, acids, etc. Made for any pressure up to 3,000 lbs.

All Homestead Valves are constructed with the patented Homestead principle which makes them seatless while the pressure is passing through.

HOMESTEAD VALVE MFG. CO.
HOMESTEAD, PA.

The Simplest and Best Cleaner on the market is



PILLEY'S

Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over.
A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.
For sale by leading Canadian jobbers.

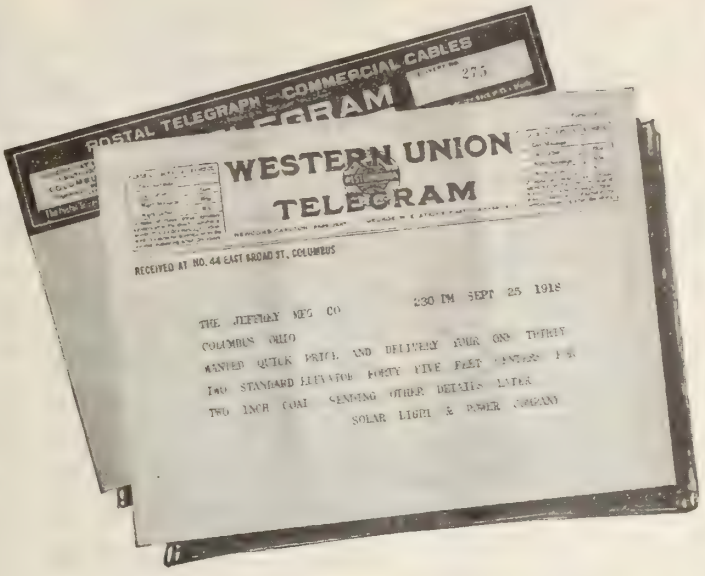
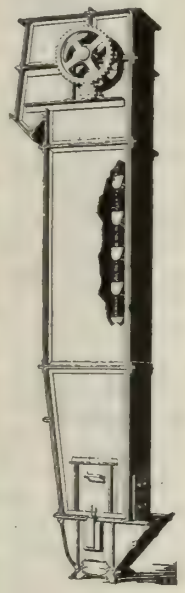
Just Telegraph Jeffrey



POSTAL TELEGRAPH — COMMERCIAL CABLES
WESTERN UNION
TELEGRAM
RECEIVED AT NO. 44 EAST BROAD ST. COLUMBUS
THE JEFFREY MFG CO
COLUMBUS OHIO
WANTED QUICK PRICE AND DELIVERY FOUR ONE THIRTY
TWO STANDARD ELEVATOR FORTY FIVE FEET CENTERS
TWO INCH COAL SENDING OTHER DETAILS LATER
SOLAR LIGHT & POWER COMPANY

From your Jeffrey Catalog on Standard Bucket Elevators select the number and feet centers, and the information as to price and delivery will be wired back to you at once.

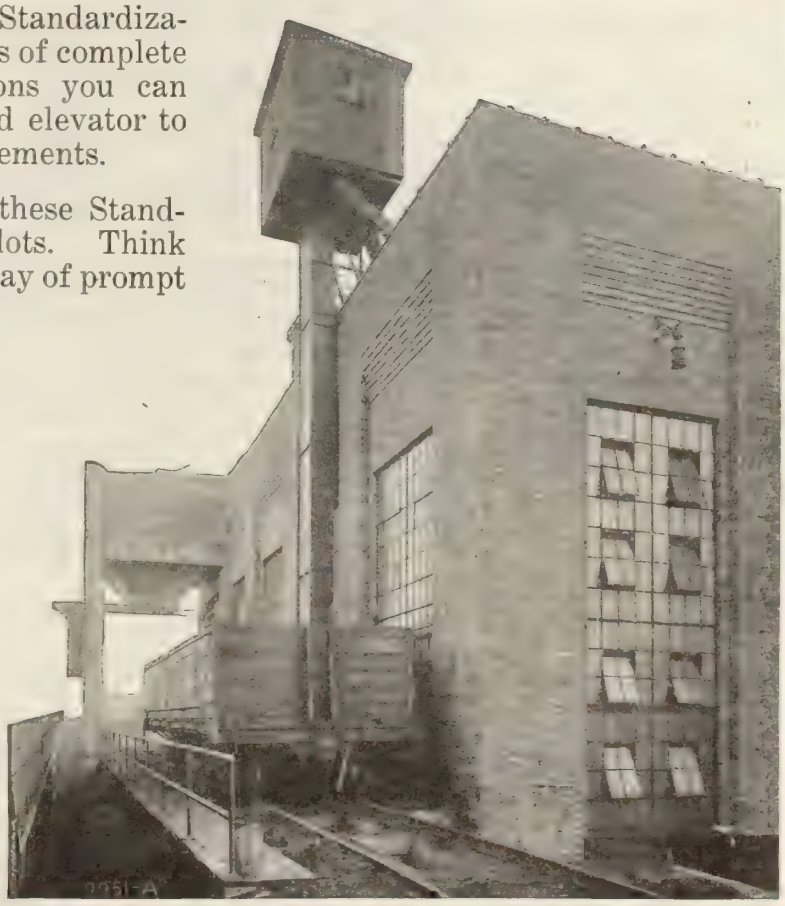


Quite an improvement over the old, endless corresponding, when it was necessary to make special layout before work on your order could be begun, isn't it?

That's the advantage of Standardization. Now from 40 pages of complete layouts and specifications you can select a tried-and-proved elevator to exactly meet your requirements.

We are manufacturing these Standard elevators in stock lots. Think what that means in the way of prompt shipment and low cost.

If you haven't Jeffrey Catalog 244 already, send for it to-day. Besides simple directions for ordering an elevator from the specifications given it contains many interesting installation views, with detailed descriptions of results had from "handling it mechanically."



At the power plant of a large implement manufacturer. Coal is fed from hack-hopper to Jeffrey Single Rollcrusher and through plate feeder to Jeffrey Standard Bucket Elevator.

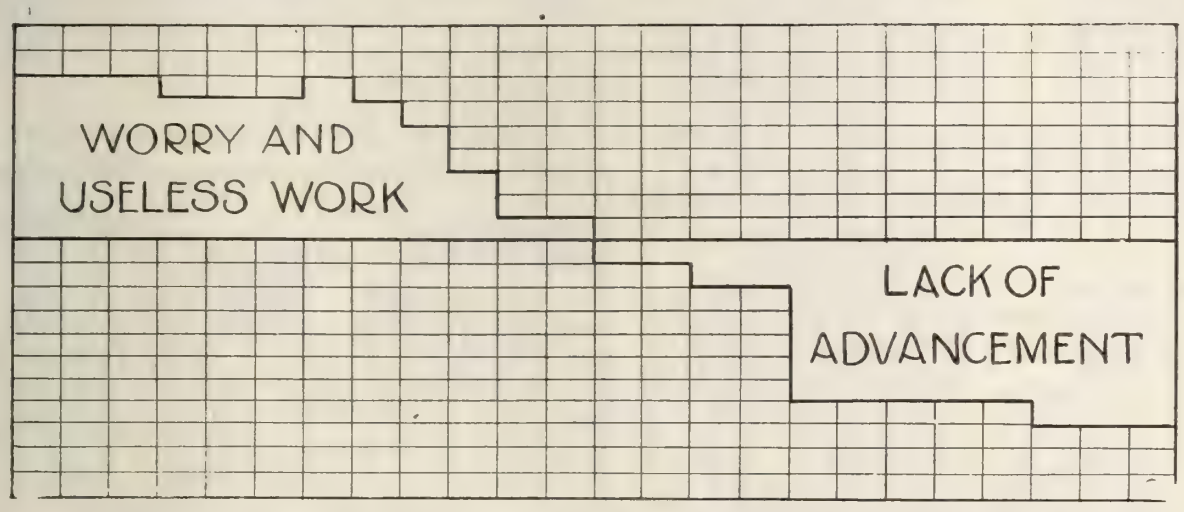
Let the *C.A.S.E.* Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

Showing ease with which Plibrico is laid in place.

PLIBRICO Increases Boiler Efficiency

PLIBRICO is a plastic refractory that makes a solid one-piece furnace lining without joints. PLIBRICO also is unexcelled for baffle construction and repairs.

It will increase the efficiency of your boiler 15 per cent. It will make your furnaces gas and air tight and greatly reduce the cost of upkeep. Can be used wherever fire brick is used. Will outwear any fire brick made.

Shipped in steel containers only. Warehouse stock carried in principal cities for immediate delivery.

Write for book on furnace building.

ALL-WAY

Flexible Spout Grease and Oil Guns

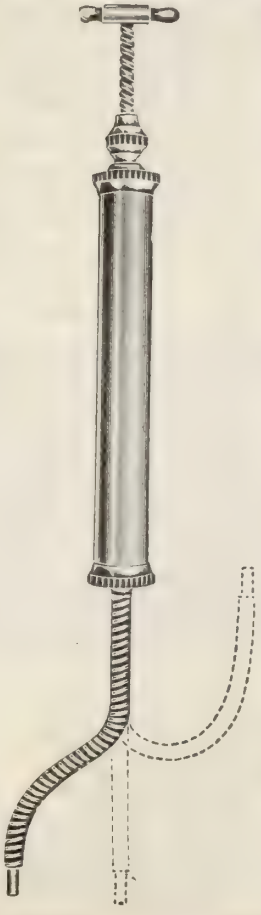
Make it easy to refill the most out-of-the-way gear cases or transmission as the flexible spout can be bent to any desired angle. The Cleaning Device at the end of the **"ALL-WAY"** spout reduces cleaning time and oil wastage to a minimum.

The **"ALL-WAY"** gun is especially useful and handy in filling lineshaft hanger reservoirs.

If your dealer cannot supply you, write us.

We also manufacture the well-known "ALL-WAY" Oil Can. Saves you 50% of your oil bill.

The Allway Oiler Mfg. Co.
196 KING STREET WEST
TORONTO, ONT.



FOR REMOVING SCALE

from Babcock, Stirling and other Water-tube Boilers and Evaporators, also for Lancashire Boiler Scaling and Rust Removing—there is no tool made to equal my

'SKATOSKALO'

Pneumatic Tube-Scaling Tool.

Simple, strong, speedy, reliable---these words describe its efficiency

Over 18 gage	102	252			

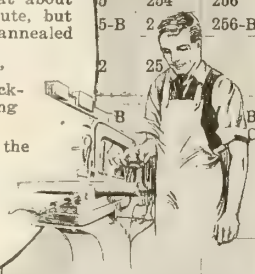
Get the S. P. M. Right

Don't run blades too fast in power machines. You can cut soft steel, if you use compound, at about 100 strokes per minute, but don't try it on unannealed tool steel.

"Haste makes waste" just as much in hack-sawing as in anything else.

Send for a copy of the Starrett Catalog No. 21 "CD" and Chart "CD"

42-983



Numbers above are those given in the Starrett General Catalog and on boxes containing the blades

Announcement

The Canadian Farnsworth Company, Engineers and Manufacturers of Condensation Pumps, Automatic Boiler Feeders, Return Steam Traps, all of the Duplex Type, and General Steam Utilities, have opened and are now operating their new factory, at 1-24 Hillingdon Avenue, Toronto. These lines formerly manufactured by the Canadian Fairbanks-Morse Company.

This new organization is under the management of Mr. W. H. Rose, who was well known to engineers as General Manager and Chief Engineer of the Geo. W. Cole, Limited, Toronto.

The Farnsworth line is thoroughly well known, having a world-wide reputation for efficiency in manufacture.

The largest order for Condensation Appliances ever placed is now in process of manufacture by this Canadian Company, for use in a Canadian plant, and consists of a number of Automatic Boiler Feeders of 1000 h.p. each, and a quantity of Lifting, Separating, Condensing Types of Machines. Photos of this installation will appear in later issues of Power House.

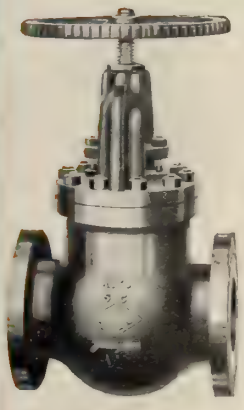
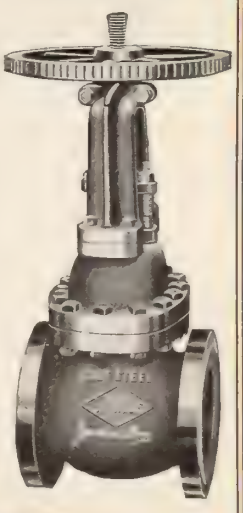
TRADE JENKINS MARK



Jenkins Bros



It pays to purchase Valves recommended by leading engineers for their modern design, quality of material, and reliable service—such valves are sure to require least attention and cost the least for upkeep.

Jenkins Valves have been on the market for over half a century; they have won the confidence of engineers and superintendents with their faultless and economical service. They endure where other valves fail because of their quality of metal, careful and scientific construction—they are made extra heavy and strong where pressure and strain is greatest.

There's a Jenkins Valve for every purpose. In making your purchase be sure you secure the genuine—you'll know them by the Diamond Trade Mark as indicated above; it's cast on the body of each valve; for your protection. Stocked by first-class dealers everywhere.

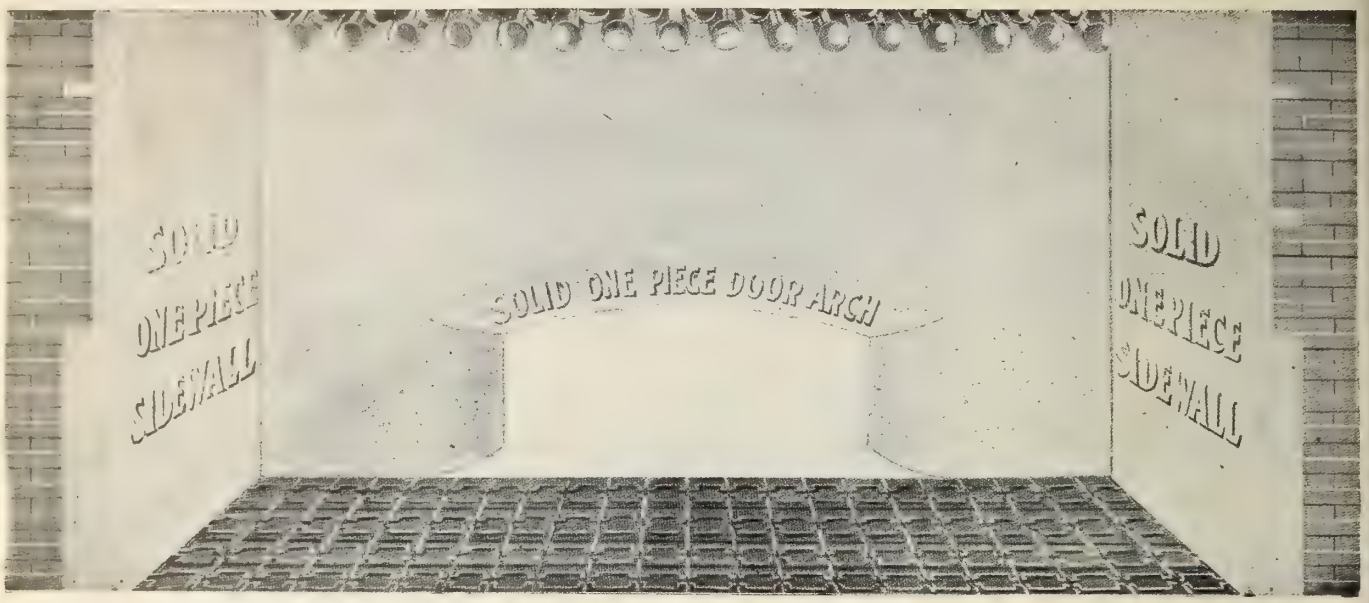
PYRO-PUTTY

TRADE MARK REG U S PAT OFF

FIRE BRICK IN PUTTY FORM

The World's Best Furnace Lining Material



Sketch above represents the fire box of a water tube boiler lined with PYRO-PUTTY

Standard fire bricks of the highest quality contain silica and aluminum oxide in almost equal proportions. This also is true of PYRO-PUTTY; therefore PYRO-PUTTY is

in reality

"The Highest Quality Fire Brick in Putty Form"

PYRO-PUTTY is superior to Standard Fire Brick of the highest quality **because** it can be installed **all in one piece,** instead of there being several hundred separate bricks and several hundred joints.

PYRO-PUTTY is also superior to other brands of Plastic Furnace Lining Material **because** it contains all natural refractories, so that when it is subjected to heat it "bakes" together naturally instead of being held together by asbestos fibre, etc., etc.

PYRO-PUTTY Should be used for—

building door arches, side walls, bridge walls, baffles, rear arches, curved stoker arches, dutch ovens and complete furnace linings of every description.

When a worn furnace lining is patched with PYRO-PUTTY the patches invariably outlast the balance of the lining

Any job that can be done with standard fire bricks can be done in less time and by unskilled labor if PYRO-PUTTY is used. And the finished job will be far more durable than a job done with standard fire bricks. **A few barrels of PYRO-PUTTY should be part of the emergency equipment of every steam power plant.**

REMEMBER— PYRO-PUTTY is put up in barrels weighing 700-lbs. each NET WEIGHT. A barrel is equivalent to 100 standard fire bricks.

STEEL TANKS AND BINS

We have made a success of building steel plate work by specializing in it.

The new additions and improvements to our boiler shops have placed us in a better position than ever before to do this work right.

Our facilities in every department have materially increased. We have the equipment and the experience to turn out this special work as it should be.

If you are confronted with any problem on this work send it in and let our Engineers give you the value of their experience.

We design and build:

CONVEYORS
SMOKE BREECHINGS
STEEL STACKS
SPARK ARRESTORS
STEEL BUCKETS
ELEVATORS
RIVETED TANKS
STEEL TANKS
STORAGE BINS
COOKERS AND DIGESTORS
STEEL GAS MAINS
REFUSE BURNERS
WELDED TANKS
SETTLING TANKS

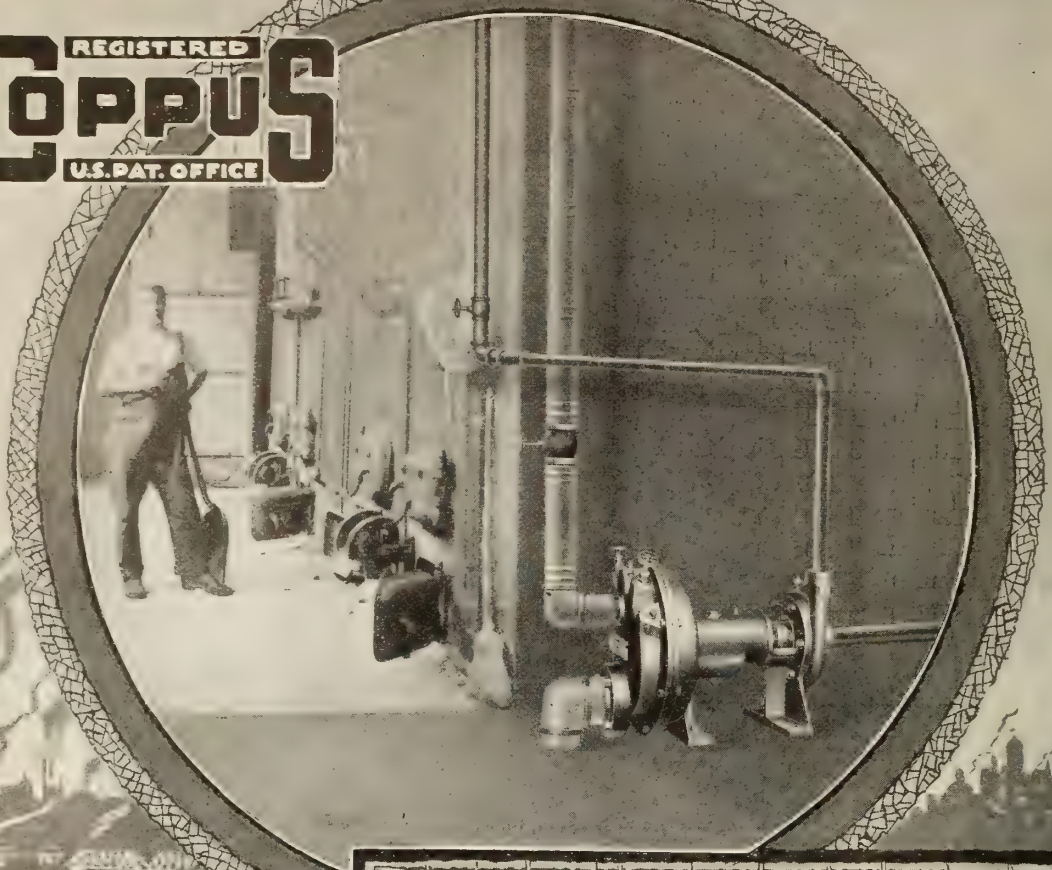
COPPUS
U.S.PAT. OFFICE



This Dependable Boiler Feeder for Your Power Plant

Possesses these distinct advantages:—

Simplicity of construction.
Steady feed without pulsation.
Easily controlled feed capacity.
Exhaust steam free from oil.
Less floor space required.
Lower upkeep—less attention required.
Higher steam economy.
Longer life—less depreciation.
Single unit construction.
Completely built in our plant.
Especially designed for the purpose.

That COPPUS Blowers are recognized as leaders in their line is evidenced in the fact that three-fourths of all the blowers made in America bear our trade-mark. Ask our engineers to show you how "COPPUS Equipment can save **you** money." Write for Blower Catalog.

The New "Emco" A332
Stop and Waste Cock

A "Two in one Fitting."

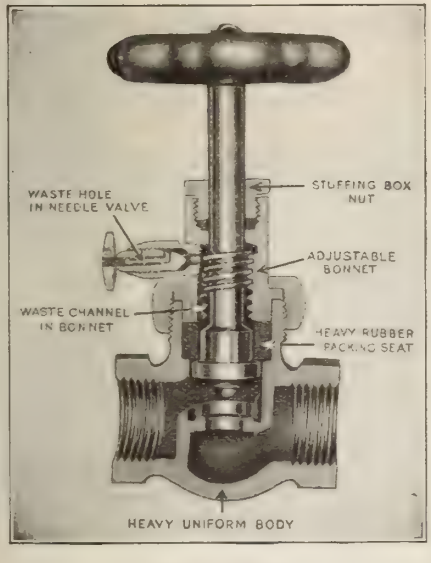
With five points of Superiority——

——five selling points in addition to the prestige that goes with the word "Emco," the trademark of its makers.

As a straight Stop-Cock or a Stop and Waste Cock it is equally adaptable.

Study the marked points in the cross sections. Pay particular attention to the arrangements for waste water:

FIRST——the adjustable bonnet which allows the needle waste valve to be placed in proper position for catching waste water.



Cross Section "Emco" A332 Stop and Waste Cock

SECOND——the needle valve which may be shut off independently to prevent a rush of water out the waste tube, when turning water on and off.

Every "Emco" is thoroughly tested before leaving our factory.

PUTS AIR TO WORK

BURN LESS AND CHEAPER FUEL

HAVE you given the same careful consideration to the operating cost of your boiler room as you have to the other departments of your plant? Because the boiler room does not come under your eye as frequently as the financial statement does is not a fair reason for letting it run day in and day out without giving it some consideration. To-day no one item of expense affects your profit and loss account more than the coal bill.

There is enough coal for you, not the kind you usually buy perhaps, but enough of cheaper grades, like hard coal screenings, to keep the boilers working. Your stack may not draw well enough to burn this cheaper fuel but a

Sturtevant
(TRADE MARK)

MECHANICAL DRAFT SYSTEM

will. It will not only burn this cheaper coal while the present shortage exists but it will place you in a position to continue using this fuel year in and year out. The system pays for itself in actual fuel saving as well as making you independent of embarrassing shortages. These are not untested theories; they are facts, practically proven in many boiler plants using the Sturtevant System.

"SAFEGUARD"
AUTOMATIC WATER GAGE

POSITIVE PROTECTION

¶ When a "Safeguard" gage glass is broken, your boiler room attendants will not be exposed to the dangers of shutting off the gage valves in the midst of escaping steam and scalding water. The quick, positive action of the "Safeguard" will automatically protect them and also prevent the burning of your boiler plates, as might happen when a boiler is nearly drained through a broken gage glass.

PERFECT OPERATION

¶ The automatic ball-valves of the "Safeguard" close only when glass is broken and positively drop away from their seats as soon as the new glass is inserted. This feature makes the gage operate perfectly at all times and wholly prevents the showing of a false water level and the dangers which might result. We feel confident that the "Safeguard" is the utmost in automatic water gage construction.

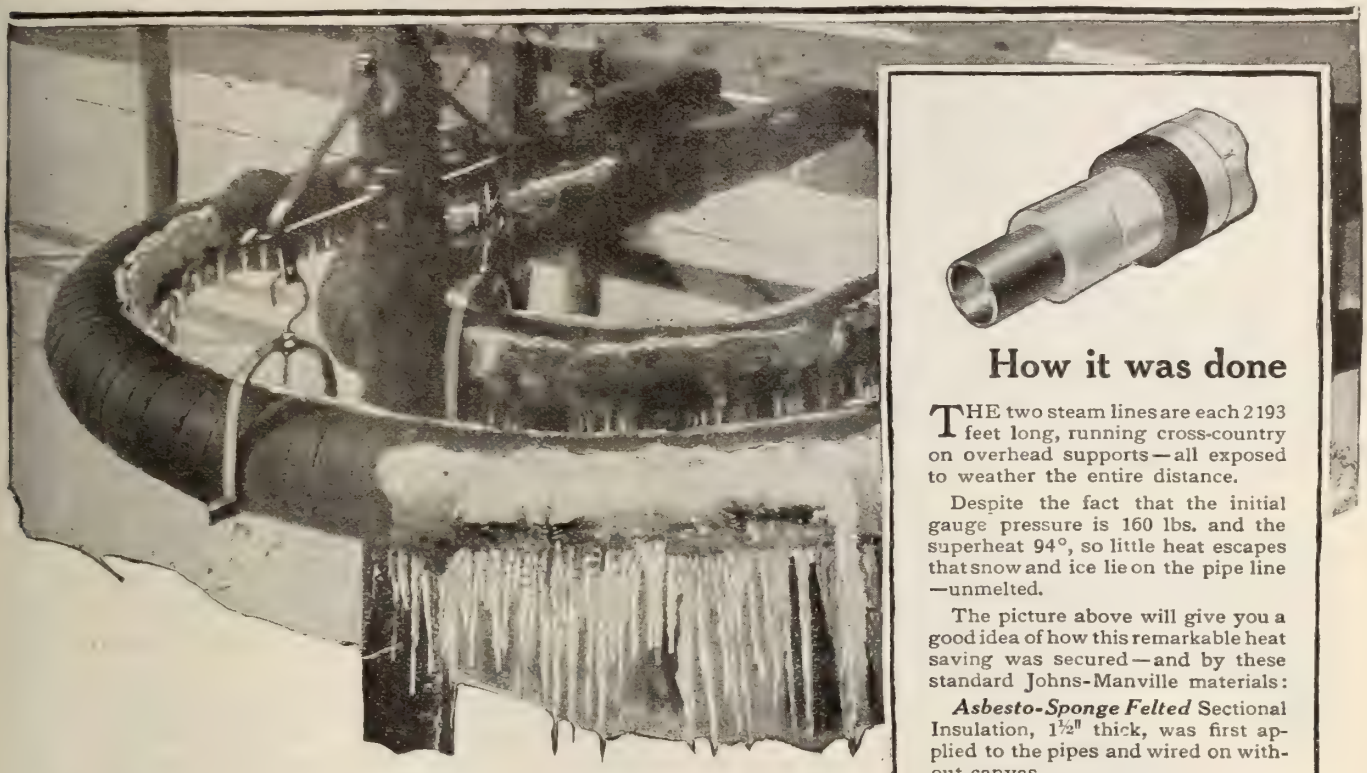
Boiling Water three inches under the ice!



How it was done

THE two steam lines are each 2193 feet long, running cross-country on overhead supports—all exposed to weather the entire distance.

Despite the fact that the initial gauge pressure is 160 lbs. and the superheat 94°, so little heat escapes that snow and ice lie on the pipe line—unmelted.

The picture above will give you a good idea of how this remarkable heat saving was secured—and by these standard Johns-Manville materials:

Asbesto-Sponge Felted Sectional Insulation, 1½" thick, was first applied to the pipes and wired on without canvas.

Johns-Manville Hair Insulation, 1½" thick, was then wrapped around the Asbesto-Sponge—and finally

3-Ply Johns-Manville Asbestos Weather-Proof Felt was wired on over the hair insulation to make an absolutely weather-proof jacket.

You will note that these are all standard Johns-Manville Insulations, included in the list below:

Asbesto-Sponge Felted, 85% Magnesia, Asbestocel, Zero Insulation, Anti-Sweat Insulation, Ammonia Insulation, Underground Steam Conduit and Insulating Cements.

H. W. JOHNS-MANVILLE CO.
New York City
10 Factories—Branches in 63 Large Cities
For Canada,
Canadian Johns-Manville Co., Ltd., Toronto

THERE is nothing new in the idea of covering pipes so that some of the heat in them may be saved.

But the exact science of maintaining temperature of fluids in pipes and other containers passing through a medium of different temperature is of comparatively recent origin.

To know the value of heat saving materials and the correct manner to use them is the basis of the science of insulation. And it is to this knowledge, combined with years of manufacturing skill, laboratory research and the application of our products, that Johns-Manville insulation owes its position today—in fact, it is the mother business of this Company.

For instance—it is doubtful if, twenty-five years ago, the conditions shown here and described in the column to the right could have been met efficiently. Now such a problem is simply a matter of engineering calculation, based on materials whose efficiency is accurately known in advance.

Accurately known because Johns-Manville insulating materials are the result of the most careful study of all materials and methods for heat saving. No Johns-Manville insulating material is advocated for use until it has proven with exactitude to be the most efficient for the purpose.

Goodyear Builds Better Hose

There was a time when men thought that rubber tires had reached their limit of quality. Then Goodyear entered the field, and, by leaving the beaten path, built the largest tire business in the world.

When Goodyear scientists and engineers turned their attention to Industrial Hose they were not satisfi d with many of the existing standards. They started from the ground up. They built for Industry's needs. Was the rubber lining unsatisfactory—Goodyear men worked till they had discovered a better one. Did a cover wear out too quickly in hard service—the knowledge gained in building automobile treads was applied to hose covers. New specifications were worked out. New formulae were developed.

The Goodyear Industrial Hose offered you today is the result of a definite policy. It is the *solution* to your hose problems—not a makeshift.

In mines, mills, foundries, shipyards, railways, and a hundred other industries, all over Canada, it is setting new standards.

There is a Goodyear Industrial Hose for every particular use—yours among them. Let a man, trained by Goodyear in hose problems, call and explain them to you. No obligation. Phone, wire or write the nearest branch.

LINCOLN ARC WELDER

Is Your Industry in this List?

If it is, you will find Lincoln Arc Welding to be an efficient, time and money-saving process that you can utilize to repair boilers, to mend cracked castings, to build up any piece of defective forged or stamped piece of metal equipment.

This list is representative of the users of Lincoln Arc Welders and the Lincoln Arc Welding Process.

In some cases two and more Lincoln Arc Welders are permanently employed on the job. In others, our welding shop is called on to do the work.

Either way assures you perfect and prompt repairs.

Where speed is necessary, as in the case of a leaky boiler, we realize that time is the all-important item. We start at once—and finish in a tenth of the time usually needed either by a replacement or other methods.

Twelve eight-retort RILEY UNDERFEED STOKERS as installed under twelve 625 H.P.B. & W. boilers at the Port Morris Station of the New York Central R.R. Co.

One feature alone of the Riley Stoker—its ***moving grates***—is worth a dozen skilled operators. Even the most skilled would find it impossible to keep the fuel bed free from holes and clinkers without dropping the efficiency by opening the firedoors.

The Riley Stoker moving grates distribute the fuel—keep the fuel bed open and porous—clean the fires—and discharge the ash and refuse. All done efficiently and economically without the attention of the operator.

It is this kind of money-making and man-releasing machinery that pays dividends, not only for the central station but for the industrial plant.

Your plant may offer large opportunities for savings. Investigate today. Complete details of the Riley Stoker construction are illustrated and described in Catalog HR-3. Copy on request.

For information on the Murphy Automatic Furnace for smaller boilers see advertisement in last issue or send for Murphy Catalog HM-3.

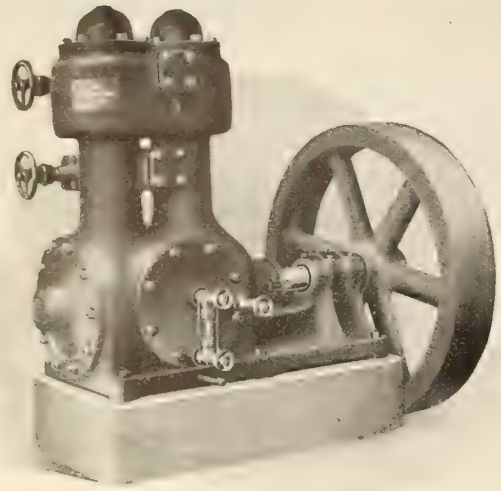
Mechanical Refrigeration



BETTER Than Ice

When saving in operating cost and saving in foodstuffs are taken into consideration, the superiority of **MECHANICAL REFRIGERATION** over refrigeration by ice is beyond comparison.

But any Refrigerating Plant, to be a success and, therefore, profitable to its owner, must be properly designed and installed to meet existing conditions.

Refrigerating installations by the York Organization are based on over 30 years' experience in building Refrigerating Machinery exclusively.

From the standpoint of service, economical operation, low upkeep cost and small amount of attention required, York Enclosed Refrigerating Machines are the best available.

Refrigerating men who do not possess the 152-page book, "Nonpareil Corkboard Insulation," will find it to their advantage to send for a copy and keep it at the plant. It answers many perplexing questions and contains much good advice. There is no charge for it.

Living Up to a Standard that Science Sets

THE merits of Nonpareil Corkboard Insulation must be attributed, in large measure, to scientific experiments conducted in the Company's laboratories. The best grade of cork to use, the exact temperatures to employ for baking, the proper pressure to apply in compressing the ground cork in the molds, and the right length of time to leave the molds in the ovens—these are all results of carefully made tests.

Briefly, scientific research sets a standard which is observed in the manufacture of Nonpareil Corkboard Insulation from the first step to the last. And as long as results can be controlled scientifically, the quality of Nonpareil Corkboard is sure to be maintained.

Armstrong Cork & Insulation Company, 1504 McGill Building, Montreal, Quebec, Canada

Also manufacturers of Nonpareil Cork Covering for cold pipes: Nonpareil High Pressure Covering for steam lines; Nonpareil Insulating Brick for boiler settings, etc.; Nonpareil Cork Machinery Isolation for deadening the noise of machines; Circle A Cork Brick for cold storage room floors, and Linolile for floors in offices, residences, etc.

POWER HOUSE

Established 1907 Canada, $2.00 per year; U.S. $2.50 per year. Published Semi-monthly

Re the Ontario Graded Certificate Act

Correspondence

Is the Second-Grade Plant Too Small?

THE suggestion given below as to the raising of the horse-power requirements for second-class engineers is a good one and should be productive of good results. The figure of 2,000 boiler horse-power mentioned is in agreement with suggestions already sent in and seems to be about the size most satisfactory to engineers. Until the Act has been in force for some time it is hardly possible to tell just how necessary such a change would be, but there is no doubt of its being desired by the majority of engineers.

The one most desirable feature of such a change is apparent in the recognition it will give to the older engineers who, while highly competent and capable of operating a plant efficiently, have not the technical training necessary for the passing of the first-class examination of the highly technical nature proposed.

The highly technically-trained man can extend his sphere of usefulness by helping those under him with the problems they encounter, too difficult for solution, without the skill which comes of much study. In this the writer of the letter below points out the help that can be given by the college-trained engineer to those that never had his advantages.

The Editor.

Sir:—I have been trying to be an engineer for quite a number of years on both large and small jobs, and have pulled through so far under some very trying conditions without any trouble worth writing home about, and I am not afraid of the new Act, although, since my school days were few, I am up against it just as hard as any other engineer. But I have thought since we were requested to suggest something re amendments to the Act, I might air my views on the subject. I do think there is room for some changes that would help all concerned.

First, I think for what the Board expects a man to know in order to get a second-class paper they have limited him a very small horse power capacity. I do not find it any more trouble to look after 1,000 H.P. than 300 H.P. I would say, draw the line at about 2,000 H.P., at least, for a second. I do not think that an employer would be mean enough to take any of the liners out of a man's pay envelope just because his papers are a grade lower than the job calls for. On the contrary, if he is equipped to think, and some of them are, he will have to engage a man with the better ticket, who will very likely want more money than the other fellow.

Now, as for the chief. I am not worrying about him if he is college-bred or not. I am working under a good one just now. Just a common, everyday man like ourselves, and came by his job honestly enough. But I sure would like to be with a good, well school-trained engineer. He is just what we want for chief. And we don't want them up a tree but right down here on the job to help us out with the problems that we don't understand. With his assistance we may become engineers yet. I think it requires something more than merely practical knowledge to be a good engineer.—Anonymous.

Will This Happen?

THIS correspondent states that the competent engineer will be driven into the field of the consulting engineer, taking over the duties which he fulfils. His qualifications are discussed and the faults of consulting practice as carried on to-day are pointed out. All this raises the old question as to whether practical or theoretical experience is the better, and the only answer that can be given is that neither is good by itself, but that the successful designing engineer requires both.

Theoretical knowledge, desirable by itself, has led to many expensive mistakes, particularly in power plant operation. Practical knowledge, on the other hand, may err in the direction of too much or too little equipment, too costly design or in other ways, which run the cost of power up.

The Editor:—

Ontario is due to have a big crop of new efficiency consulting engineers. Recently I spent several weeks in your "flu-filled" but beautiful city, and, of course, expended a large part of my holiday time in visiting power plants and talking to the men in charge. Many of these men are middle-aged, some of them even old, but all are strong and hearty. Most of them have spent a large part of their lives as operating engineers and chiefs.

Certain ideas appear to be like the "flue"—catching—the germ was in my own brain and it grew rapidly when it came in contact with others. Four different men, with no prompting from myself, informed me they intended putting out their shingle as efficiency and consulting power plant engineers. Can you beat it? These men were formerly first-class license-holders with the O.A.S.E., and were disinclined to pass another examination. They claim they are perfectly qualified to act as power plant experts in its real meaning, more so than many of the regular consulting engineers, who have had little or no experience as men in actual charge of plants in operation.

One of the men defined efficiency of power plants as "elimination of wastes, caused mainly by faulty engineering equipment, designed or recommended by incompetent consulting engineers."

In the United States many practical power plant engineers have started in this profession and have found it a lucrative field, most of them gaining considerable success. The capable operating engineer often meets with scant tolerance at the hands of the owner, the successful consulting engineer always gets the "glad hand" from the same source.

What makes me "chortle" is the fact that such consulting engineers can decide what kind of equipment is to be installed and receive a big wad of "long green" for his advice and supervision, while the poor boob who operates the outfit puts in long hours, night study, and passes a stiff examination, for small pay in comparison to the efficiency man. Remember, I could only visit a very few of the middle-aged engineers in Toronto, there

must be dozens in your city who are nursing this same idea. I had it myself, and am now wondering if, with a few dozen new efficiency experts, will there be enough owners requiring, or thinking they require, this kind of service?

Is it not amusing? Different times I have known operating engineers to recommend the installation of certain apparatus and they have been rather roughly turned down by the owners. Afterwards the owners have paid out good money to consulting engineers for advising them to install the same apparatus or something inferior. What tends to make the practical engineer a successful consulting engineer is his skepticism. He has an insistent desire to be "shown"! Unwillingness to take all things printed in papers for granted, this is a real asset to a successful engineer, he tries things out and separates the real from the doubtful. The technical-taught consulting engineer has not this advantage. It is unsafe to assume that a thing cannot be done because someone says so, and it is just as unsafe to assume something can be done for the same reason. This is where a practical experience is of wonderful help to the consulting engineer.

Of course, practical experience alone is of little use to a real engineer, consulting or operating, without considerable technical knowledge. No engineer worthy of the name is anything else than an efficiency engineer; his whole course of study and practice is to adapt economically nature's laws to practical needs.

A lot of special equipment has been devised which enables improvements to be made, tending to save labor, fuel, water, etc., and many new appliances are made only to sell. The practical, technical, consulting men will not be fooled by the latter.

It looks to me that the stationary engineer, as a power plant consulting engineer, acting not for one plant but for any plant, is due to arrive. Boost him along!

M. A. CULLING.

A Voice From Quebec

IT is seldom that we receive a letter which recognizes the relative value of the technical and practical in stationary engineering so well as the one below. The different avenues open to the engineer for the acquisition of knowledge are discussed and the sound advice given to use the bookshelf for the obtaining of knowledge instead of as an amusement.

The Editor.

I have followed with great interest, sometimes with amusement, and I am afraid sometimes with a certain amount of cynicism the many discussions aired by my brother engineers in POWER HOUSE on the graded certificate now in force in the province of Ontario. Our friend, Mr. Noble, makes rather a stinging remark when he calls the man without technical training a wop. In slang phraseology I take this to mean a fool. I have in my mind's eye, here in the city of Montreal, a splendid mechanical engineer, yet with not a particle of technical education. I have spoken to this man and his reply was: "What's the use? I get on just the same," and I venture to assert that the majority of engineers are of the same stamp; too much trouble to study. That is why I fail to see why any good, practical engineer of the present day should not be a very fair technical man. We shall find that the engineer of the future will be just as good on technical points as he is on practical, but at present I ask my brother engineers to follow POWER HOUSE articles and read, mark, learn and inwardly digest, for by them the engineer can learn better than by all the technical books, for every one is elementary and so plain to the dullest mind. If these instructions are carried out our friend will get the craze or bug as many hundreds have done before, and he will be able to cross swords with the consulting engineer instead of standing by and looking very foolish when that most estimable man is pulling the wool over his eyes by rattling away in technical patter.

I must say I don't agree with him in raising the B.H.P. for second and third class engineers or (tickets). My reason for this is that so many engineers who make first-class operators when the chief is in the plant seem to lose their initiative when trouble comes, the sequel is big trouble and plenty.

In finishing up my few remarks on our friend's letter, I must not forget his personal friendship with Mr. Smith. It goes to prove that the late Mr. Smith was not too proud too learn from a practical man. I myself ask POWER HOUSE many technical questions on points I am not quite clear on, and I have charge of the largest power plant in Canada, and am well advanced in years, and I tender great thanks to our present Associate Editor, Mr. Fenner, for helping me on matters technical.

In passing comments on our friend Mr. Stone's letter, I emphasize every word. No position in this world, even in engineering, is gained by remaining in a stagnant pool of knowledge.

I smile at his reference to a good library (engineering), for in that he echoes my sentiments. I only wish every engineer would do likewise, and when he is collecting his books for the library to remember they are for use not to ornament his bookcase. In concluding my remarks to Mr. Stone, I would remind him that we are getting more enlightened every day, and present-day conditions call for a technical man as well as a good, practical man to take charge of an up-to-date power plant, so please, Mr. Stone, persevere.

In concluding my few remarks, I must pay a tribute to the letter of Justice II., as a reader of very fair mind and gifted with knowledge and common-sense. There is no chief to-day who is worth a row of pins who is not gifted with a fair amount of technical knowledge, and it is only a cheap man playing on the reserve of the plant which sooner or later will have to be remedied. Now, Mr. Editor, I would like you to put these last few lines in blazing letters.

I hope the certificates of Ontario will not develop into the huge joke they are in Quebec. It would surprise a good many readers, but it is true here in the city of Montreal one of our largest plants, 1,000 boiler horse power, has a man with a fourth-class certificate in charge and the chief engineer of another large installation has no certificate at all. There are also other examples too numerous to mention. (Why bother reading books in the province of Quebec). I sincerely hope that these few lines may meet the eye of the people mentioned.

HENRY WRIGHT.

From the high prices of the year the aggregate market value of the common stocks of 20 leading industrial corporations has slumped approximately $560,000,000. A Wall Street compilation puts the combined market value of these stocks at the recent highs at $2,662,966,346. That figure is now around $2,100,000,000. That gives an idea of the extent of the decline in Wall Street security values. This does not take into consideration the fall in railroad stocks, in Liberty bonds, in railroad bonds, in fact, in all issues. General Motors common stock has slumped close to $250,000,000 in market value from the high price of 1919. This stock is not included in the 20 used in the compilation.

BY THE time a young man figures out the cost of a kitchen table, and stove, and a few sticks for the dining-room and bedroom, and still persists in the drift of matrimony—let us arise and shout: "There is a man!"

THE head of a New York grocery concern says prices will stay up for two years yet. If that chap ever predicted anything else he'd lose his job as the drum major in the grocery league.

Present Day Synchronous Motor Design

The Following Article Enters Into the Design and Construction of the Present-Day Synchronous Motor and Also Points Out Their Many Advantages for Industrial Power Purposes

By W. S. LOCKHART

Engineering Co. of Canada

PRESENT day Synchronous Motors of the best design are not the modified Alternators, of a few years ago. The earlier type of Synchronous Motors were not self-starting, they were nothing more nor less than Alternators run as Motors, and thus their applications were limited. Some Synchronous Motors of the present day are nothing more nor less than Standard Alternators with squirrel cage windings about their rotors, however, the better class of Synchronous Motors is designed from start to finish as Motors, and is really a combination of a Synchronous Motor and an Induction Motor. They are self-starting, have good starting and pull-in characteristics, and will carry as high as 400 per cent of full load for short periods, without pulling out.

They are now used on practically every drive where a constant speed is required, such as big air compressors and ammonia compressors, heavy jaw crushers, line shafts, big pumps, fans and heavy rolls. Synchronous Motors are run efficiently as low as 75 r.p.m., and for this reason are especially adapted for direct connecting to air and ammonia compressors.

They can be used as Condensers floating on the line for power factor correction only, or while operating at unity power factor load may be taken off, or the fields may be over excited thus drawing leading current from the line, improving the power factor of the system and at the same time do mechanical work.

Present day Synchronous Motors have all the characteristics of Induction Motors while starting. In the first designs of squirrel cage windings if a high resistance winding was used, it would give the motor an excellent starting torque, but unfortunately high starting torque and high pull-in torque did not go together, therefore, it was a case of sacrificing one for the other. At the present time manufacturers specializing in Synchronous Motors have overcome this difficulty by developing a special compound squirrel cage winding, and by so doing are now able to obtain excellent starting and pull-in characteristics without drawing excessive kva. from the line.

Mechanical Design

The Stator of the more modern type of Synchronous Motor consists of a core, as in the Synchronous Generator, built up of laminated steel segments rigidly anchored to the cast iron frame, provision being made, of course, at intervals for vent ducts in the assembled core. The ordinary double layer winding is used and these armature coils are placed in the open slots of the core and held in place by fibre or wood wedges. The part slot winding is being used to a great extent by one manufacturing concern, and this means of winding along with a specially designed rotor produces a current and voltage wave form very close to the sine wave.

FIG. 3—CORE BEFORE WINDING—NOTE THE SLOTS IN PUNCHINGS FOR DAMPER BARS.

The rotor consists of a circular spider having a web or spoke construction, according to the size and speed of the motor. One way of mounting collector rings as in the case of engine type Synchronous Motors, is by placing the rings on the extension of the heavy hub. This method of mounting collector rings symplifies matters in the erection of the motor as the rotor may be shipped out on the job and pressed on the engine shaft without any further trouble, from shrinking collector rings on the shaft.

Rotor spiders for slow speeds are usually made of cast iron, while in the high speed type, cast steel is used. Pole pieces are built up of soft sheet steel punchings of high magnetic quality held together with heavy steel rivets, passing through the complete pole. In slow speed machines, pole pieces are usually bolted on the periphery of the spider, while in the high speed type the dove tail, T tail or anchored type construction is usually adopted. See Figs. 1, 2, 3, and 4.

The result obtained from converting the Standard Alternator into an Induction Motor would be as follows: The air gap would be large and the pole embrace small, say from 50 to 65 per cent., and if we used the same whole slot winding in the Stator as in the Alternator, the combined result would be large magnetizing currents, very large current from the line in starting and thus poor starting torque at a reasonable starting current.

This difficulty has been overcome by Synchronous Motor experts of to-day, by specially designing the Rotor so as to get a very small air gap with a large pole embrace, say 70 to 80 per cent. This large pole embrace insures better wave form than a short blunt pole tip would give, and also gives a more evenly distrited squirrel cage winding about the Rotor. The combined result of this construction together with the part slot winding, see Figs. 5 and 6, of the stator gives us a motor of small magnetizing current and high starting torque at a very reasonable amount of starting current.

FIG. 4—ANCHORED TYPE POLE.

To complete this type of construction, a series of damper bars are inserted in slots in the pole faces, and joined through end plates. End plates of each pole are connected together thus forming a closed ring around the rotor. This produces a squirrel cage winding similar to the Rotor of an Induction Motor, see Fig. 7. The damper bars are selected with special reference to starting torque. Damper bars of high resistance metal give a higher starting torque than those of lower resistance. When the metal of lower resistance is used the starting torque is lower, but the pull-in torque is much higher. The resistance of the damp-

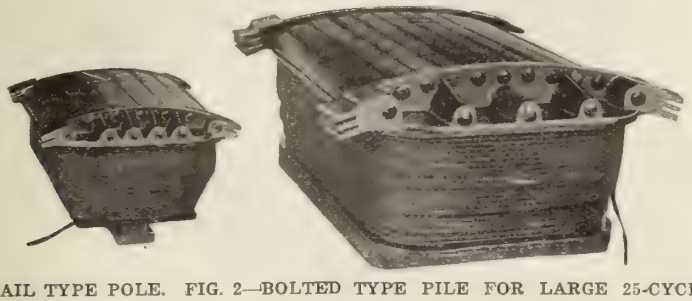

FIG. 1—T TAIL TYPE POLE. FIG. 2—BOLTED TYPE PILE FOR LARGE 25-CYCLE MOTOR.

er bars depends also on the size of this cross section.

The present Synchronous Motor is as easy to start as the ordinary Induction Motor, and does not require any special care to put it on the line in Synchonronism with the other apparatus. By

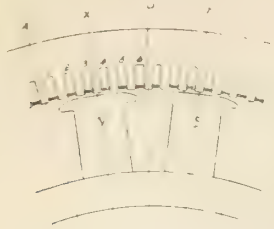

FIG. 5—EXAMPLE OF EVEN SLOT WINDING, 6SLOTS TO EACH POLE PITCH. SINCE THERE ARE THREE PHASES THIS MEANS 2 SLOTS PER PHASE PER POLE FROM A TO B IS ONE POLE PITCH.

throwing in starting switch we apply, say 50 per cent. line voltage to the motor. The motor starts to build up in speed, and at roughly 60 per cent. full speed, the starting switch is opened and the running switch is closed, thus applying full line voltage to the motor. The speed still further increases, and as the motor approaches synchronous speed the ammeter needle fluctuates somewhat, when this quiets down the field switch is closed and the motor is on the line.

This last performance of closing the field switch does not require any great skill on the part of the operator, as the motor will go on the line as long as the difference is not greater than five Electrical degrees.

Electrical Characteristics

Without going too deeply into the electrical calculations, let us take three practical cases of a Synchronous Motor operating on a line, and show by vector diagrams the resultant k.v.a., and power factor of system thus obtained. Let us assume our original system of 1,200 k.v.r. output operating at 80 per cent., lagging power factor and a Synchronous Motor of 400 k.v.a., nominal capacity to be added to the system.

First Case. An arc with 100 radius will indicate power factor circle. Draw the radius line or "vector" O A through point X, the intersection of the 80 per cent power factor line with the circle. This "Vector" will represent the 1,200 kva. output at per cent. power factor (length indicating k.v.a., and position indicating power factor). The Synchronous Motor is to be added driving a mechanical load of, say 250 k.w., including motor losses, at unity power factor. Draw the vertical line A B representing 250 k.w. vertical because at unity power factor. It will be seen that the added 250 k.w., of load at unity power factor, improves the power factor of the whole system. Now, draw the line O B, which by length indicates the new output 1,450 k.v.a., and by position the new power factor of the system, the point Y, where O B intersects power factor circle, giving the power factor at 86 per cent.

Second Case. Now, increase field excitation of the motor to give leading power factor until it is carrying its full capacity of 400 k.v.a., while still driving the same mechanical load. In this case the motor may be represented by a triangle ABC, the side AB representing the mechanical output plus losses in motor (disregarding increase in motor losses due to increased excitation), the side AC representing the 400 k.v.a. in-

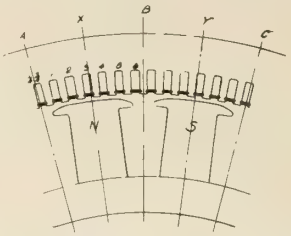

FIG. 6—EXAMPLE OF PART SLOT WINDING, 6¾ SLOTS TO EACH POLE PITCH, OR 2¼ SLOTS PER PHASE PER POLE.

put of motor at leading power factor, and side BC the wattless component at leading power factor 312 k.v.a., which is introduced into the system by the motor.

The new "Vector" O C by length, indicates the new output 1,280 k.v.a., and by position the new power factor of the system 05 per cent.

The power factor of the motor is the ratio of A B to A C = 63.7 per cent. leading.

Third Case.—Now, remove the mechanical load the motor was driving and still further increase the excitation until the motor carries its safe continuous capacity, 90 per cent. of nominal or 360 kva., at approximately zero P.F. (This will tax the motor field to its safe operating temperature limits on account of low P.F.).

The losses in the motor, say, 25kw., are now the only power load it carries. As in Case 2, the motor is represented by a triangle ADE, of which AD represents the power load of 25 kw.losses, AE the motor input, 360 kva., and DE the wattless component at leading power factor, 359 kva., introduced by the motor.

As in case 1, and in case 2, a new "Vector" OE indicates by length, the new output 1,050 k.v.a., and by position the new factor of the system 94 per cent. The power factor motor is ratio of A D to A E = 7 per cent. leading.

From the foregoing it is seen that in the second case there is even more corrective effect than in the third case, and the motor is at the same time doing a large amount of mechanical work.

The three cases may be summed up as follows (on a 1,200 k.v.a., system Synchronous Motor of 400 k.v.a. capacity).

First Case.—The Synchonous Motor at unity power factor, carrying 250 kw., load raises the lagging power factor of system from 80 to 86 per cent.

Second Case. The Synchronous Motor at 63.7 per cent. leading power factor, while carrying 250 k.w., load, raises the lagging power factor of system from 80 to 95 per cent.

Third Case. The Synchronous Motor at 7 per cent leading power factor, while carrying load of 25 k.w (losses in motor), raises the lagging power factor of system from 80 to 94 per cent.

General Uses

Synchronous Motors are being used today on practically any constant speed load. On account of their high efficiency and ruggedness, they are being used to drive sucessfully large jaw crushers, where tremendous variatians of load occur, air and ammonia compressors direct connected, and running as low as 72 r.p.m., reciprocating pumps (in this case starting conditions are usually relieved by a by-pass so that the motor can easily take care of the load and pull it into step without excessive k.v.a. input) centrifugal pumps, motor generator sets, etc.

We should not overlook the limitations to Synchronous Motor drive, such as small loads under 100 h.p., except perhaps in motor generator sets, also where frequent starting or stopping is necessary or where adjustable speed is required, and lastly, as Synchronous Motors are at present designed they can-

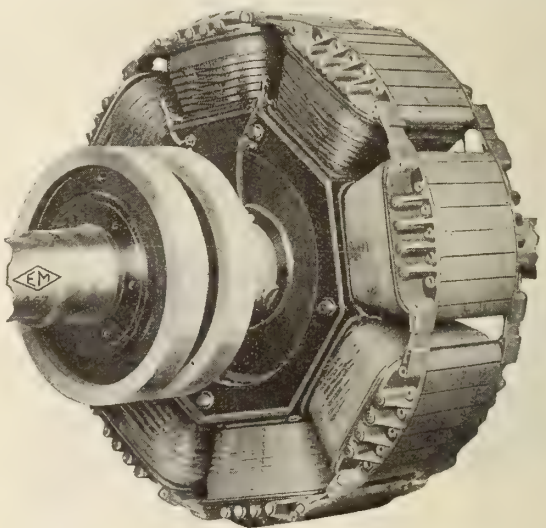

FIG. 7—EIGHT POLE ROTER, SHOWING SLOTS IN POLE FACES AND SQUIRREL CAGE WINDING

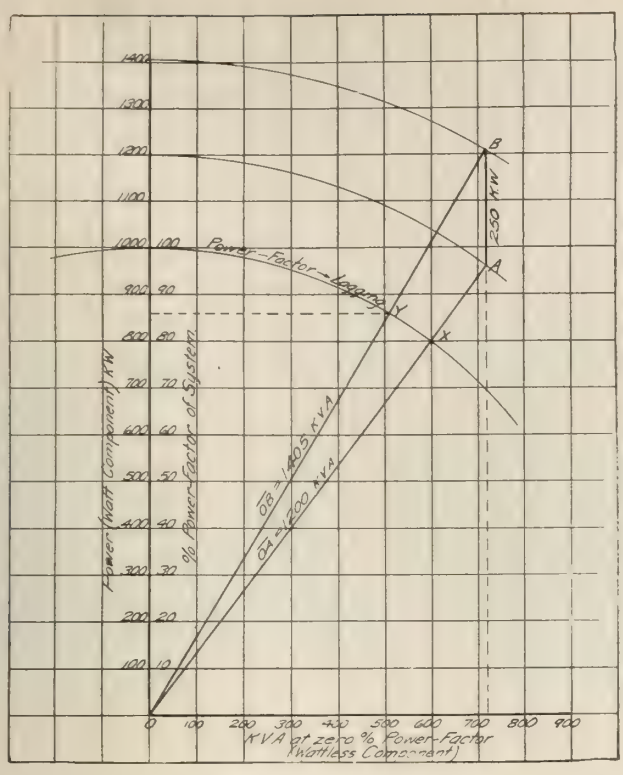
not start up under full load without exvessive kva. in-put. This last applies to rubber mills, cement mills, and line shafting, where the motor is required to start up practically a full load, In these cases Synchronous Motors are at the present time operating successfully by the use of properly de-



FIRST CASE CURVE—1.

signed mechanical or magnetic clutches, and this additional cost of clutch should not be considered where we get such increased efficiency and high power factor, conditions as in the Synchronous Motor.

Perhaps the greatest use of Synchronous Motors to-day is for power factor correction. Synchronous Motors and Synhcronous Condensers, in order to give the best results should be located near the causes of low power factor, namely, the Induction Motor load. That is why it is much better to induce the power customers to install Synchronous apparatus of their own than it is to rely entirely upon the Synchronous Condenser of the central station.

Low power factor means waste all the way from the prime movers through the generating equipment, through the transformers, transmission lines distributing circuit clear to the motors. There is no exact place where the cost can be divided, so it is necessary that the power Company and the power customer work in harmony together. Low power factor means poor voltage regulation that is a very bad thing for the power company, as everybody knows, and it is also a very bad thing for the customer. Since apparatus is invariably over-loaded where voltage is lowered, coils are burned out and other break-downs frequently occur.

The torque of Induction Motors falls off as the square of the voltage, so many motors become stalled and do not carry their load, others operate at a much lower efficiency. The copper losses increase as the square of the current Current increases as power factor decreases, therefore the losses mount up at an alarming rate. This means a waste of coal to the power company, and a waste of money to the power customer, who has to pay for a certain amount of power which never reaches the motor.

People do not realize how much they are affected by power factor, many seem to think that it affects the other fellow and, that, of course, is a very bad thing, but they cannot believe that it exists right in their own plant. The most important cause of low power factor is the Induction Motor running at part load. The customer has grown up with the habit of buying motors larger than the load requires, this has had a very bad effect on the power factor of the circuit. The average Induction Motor at full load has a very satisfactory power factor when operating at half ... or lower the power factor is very poor.

Builders of machine tools and other types of motor driven apparatus are frequently responsible for bad power factor of motors. They often times recommend a larger motor than the machine really requires. This sounds like good advice to the customer, and he puts in an over-size motor and operates it at a very unsatisfactory power factor.

THIRD CASE CURVE—3.

Some of the Principles Underlying Refrigeration

A Brief Account of the More Elementary Theory of Refrigerating Machinery and of the Various Methods by Which Refrigeration is Obtained

By ADAM TAYLOR

OWING to the graded certificate coming into force this year, a large number of engineers are showing signs of nervousness about the examinations, and in looking over the at I find one of the things that we are to be examined in is refrigeration. For this reason it is the purpose of this writer to try in as plain language as possible to give the engineers an idea of what the principles of refrigeration are.

A number of books are published on the subject, but they are so technical in their scope, that they leave the reader in a haze, and his last stage is worse than the first.

We will start with the gases first. All gases have been liquefied, that is to say, when they are subjected to a given pressure and temperature they become liquid. When a gas has become liquid and it is allowed by a reduction in pressure to become a gas again, it takes up a definite quantity of heat from whatever it comes in contact with. To give an illustration, let the reader take a long breath, open his mouth and breathe on the back of his hand, the sensation is warm. Now take another breath compress the lips and blow on the back of the hand, the sensation is cold. In the first instance you had no compression, therefore no expansion. In the second instance you had both compression and, after leaving your lips, expansion. That is the principle of refrigeration, only machines are built to do the work, and a gas is employed that has a low boiling point so as to get the desired effect.

Air, carbon dioxide, sulphur dioxide, and ammonia are among some of the gases that are used as refrigerants, but as ammonia is the most used, it will be taken up first.

Ammonia is a chemical combination of two gases, hydrogen and nitrogen. It is easily liquified at 90 lb. pressure, and by the use of cooling meter at 60 deg. F. Ammonia has a low boiling point, 28.5 deg. F. below zero (The boiling point of water is 212 deg. F. below zero), which makes it suitable for producing low temperatures.

We will follow the ammonia gas through the machine. The compressor sucks it in and discharges it to the condenser. In passing through the compressor its pressure is increased, and the creating of this pressure increases the temperature of the gas. This heat is taken out by the cooling water on the condenser, and the ammonia becomes a liquid. It is next passed on through a small pipe to the cooler or rooms that are to be cooled, it is then allowed to enter the pipes at a very much reduced pressure. This reduction in pressure will cause it to boil rapidly and turns into gas. The compresser then sucks away this gas as quickly as it is given off through boiling. In boiling the ammonia is absorbing heat from its surroundings, and this is the process that is going on all the time.

A mistaken idea that some engineers have is that the expansion valve is the one that does the work, whereas it is the suction side that counts, the more rapidly you can pull away the gas after it has been given off and before it can create a pressure, the more you can open the supply valve (expansion), and let more ammonia in; the more ammonia circulated the more refrigeration is done. There are various types of compressers made to handle ammonia, but the principle is the same in them all. When we consider the principles of refrigeration and the effects produced, it is simply exchange of heat. When we compress the ammonia gas, and after we abstract from it the resulting heat, and that, due to its liquifaction in the condenser, we have a liquid, under

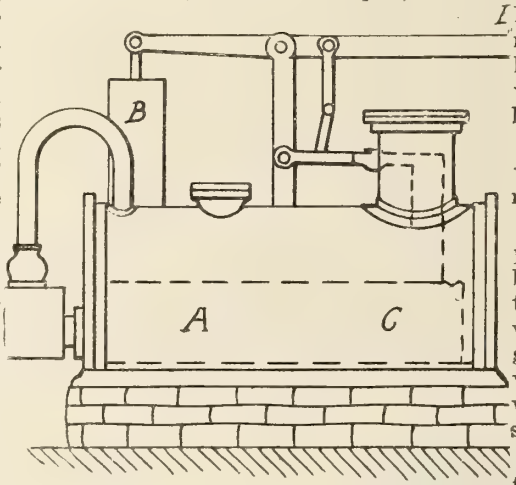

DIAGRAM OF REFRIGERATING SYSTEM.

high pressure, which is capable of becoming a gas under normal pressure. In doing so it must absorb a certain amount of heat, otherwise the conversion from liquid to gas could not be accomplished.

As I stated before it is the evaporation of the liquid ammonia that does the work, so that nothing but gas should return to the compressor. In practice this is not the case as a small quantity of liquid is allowed to get back to the machine. If nothing but gas came back to the compressor there would be no frost showing on the suction line, as ammonia gas has little effect in absorbing heat. Some engineers will state definitely that nothing but dry gas comes back to their machines, but, when there is frost on suction pipes and machines then there is unevaporated ammonia there. It is possible to limit this loss by watching very closely the temperature of the discharge pipe.

There are quite a few little things that crop up to add to a refrigerating engineer's worries. He may get his machine started up all right, the discharge and suction pressures may be right, the water on the condensers O. K., and plenty of ammonia in the system according to his gauge glass on the receiver, but it is not doing nearly the work he should do, the thing is to locate the trouble. Sometimes we may get ammonia containing impurities, and if ammonia contains more than two per cent. impurities it has a deterimental effect on the refrigerating qualities of the ammonia, watch for that. Take a small quantity of the anhydrous ammonia measured in a glass, and let it all evaporate in the open air, and see what is left, the impurities are all left behind. Theoretically ammonia will not disassociate unless under high temperatures, but the practical engineer knows different. Ammonia will seperate into the two gases, hydrogen and nitrogen, and these are so called permanent gases, they remain seperate and will not liquify and retard the work of the ammonia. Sometimes these two gases will have a certain percentage of another gas which has a bad effect on the throat and lungs.

Keep the machine free from gases, you will find them at the highest point of the machine.

There is generally a ½-inch valve and pipe there for purging out, some advise blowing it off into a pail of water, but the best way I have found is to open the valve a very little and light the escaping gas and burn it out. Hydrogen burns with a blue flame, pure ammonia gas will not burn itself, and one can readily see when the permanent gases are all out.

Sometimes you will get a gas there that will not burn, the only thing then is the pail of water with a short piece of hose, and when the gas is all out, and the ammonia gas starts to come you will hear a loud cracking noise as the ammonia and water mix.

The accompanying illustration shows one of the first in making machines. It consists of a cylinder containing sulphuric acid marked A, an air pump marked B, so arranged that it could be connected to the mouth of the carafe, and an agitator, G, which is so coupled to the air pump lever that it will be operated by the working of the pump to keep the sulphuric acid in the cylinder in motion.

The machine is where water is made to freeze itself. The pump is worked, and a vacuum is created where the water is and causes the water to boil at a temperature below 2 deg. F. The sulphuric acid absorbs the vapor given off by the water, in turn taking its heat from what is in the vessel and thus causing it to freeze and become ice.

This is called cooling off liquids by their own evaporation in vacuo.

Power Plant Features of a By-Product Coke Oven

The By-Product Coke Oven, While Making Gas and Coke Instead of Generating Power, Has Many Features of Interest to the Power Plant Engineer in the Handling of the Coal and Coke and the Power Plant

By W. F. SUTHERLAND

A GENERAL VIEW OF THE BY-PRODUCT COKE OVENS.

COAL is one of the most commonplace and prosaic of our minerals, yet it is doubtful if any other single mineral has within itself the potentialities for man's welfare that exist in coal. In the power plant, while it is burned for the production of heat and power, both important in themselves, its possibilities are not so readily apparent, and the coke oven is the starting point from which are obtained the dyes, explosives, fertilizers and drugs so common to-day.

The coke oven in itself is, perhaps, a trifle out of the usual field of stationary engineering, but a study of its functioning will prove fascinating to the engineer, and a visit to a modern by-product plant will provide much information of interest concerning strictly power plant subjects, for in the control of the various operations of the plant power plant equipment finds a most important place.

The following article is descriptive of the new coke ovens of the Steel Company of Canada, at Hamilton, and in addition to describing the power plant equipment first gives a short account of the operating characteristics of the ovens themselves.

The art of making coke, up to comparatively recent times, made comparatively little advance, and the beehive oven formerly used is still to be found in many places. This oven, merely a brick-lined chamber in which the coal was heated by the combustion of a portion of the charge, wasted all the gas and other valuable by-products obtained from the coal, although it made good coke and had the advantage of cheapness.

The modern by-product oven, a recent development, on the other hand, conserves the gas, tar and nitrogen content, while making an excellent coke suitable for blast furnace or other uses.

Coke is very light as compared to the coal from which it is made, and it is estimated that 50 per cent. of its volume is air space, and for metallurgical purposes should be strong, porous and regular in composition. The amount of sulphur is also important as an excess causes expense in its elimination in the blast furnace.

Since the physical properties and chemical composition of the coke are of such moment, the grade of coal used is of importance. In the present case two kinds are employed, one running about 34 per cent. volatile and the other about 17 per cent. Both run about 8 to 9 per cent. ash content and contain .8 per cent. or less of sulphur.

The coal is unloaded into a receiving pit capable of handling two cars and from this is lifted by an apron conveyor onto a 30-in. belt conveyor. This conveyor, driven by a 50 h.p. motor, carries the coal to the top of the coal-handling plant where it is delivered into the crusher. The crushing is done by a Bradford breaker and on being crushed the coal is screened, the slate, etc., being separated and delivered to a reject bin.

From the crusher the coal is delivered into either one of two mixing bins depending on its volatile content and from these it is drawn out onto the mixing table one floor below. This table consists of two short apron conveyors in line, with their upper surfaces travelling towards each other. The depth of coal on each conveyor is regulated by means of independently adjustable gates. By means of the gates any desired percentage of high and low volatile coals is obtained; at the present time the mixture runs about 85 per cent. high and 15 per cent. low volatile.

From the mixing table the coal now composed of the two grades goes to a hammer mill below, where it is pulverized fine enough for eighty per cent. to pass a ⅛-in. mesh screen. From the pulverizer the coal is conveyed by belt conveyors to a transfer tower and then at right angles by another conveyor to a coal storage bunker holding 1,400 tons. The hammer mill was supplied by the Williams Patent Pulverizer & Crusher Co., and is driven by a 300 h.p. three-phase Canadian Westinghouse induction motor of the wound rotor type. The mixing table is driven by a 10 h.p. squirrel cage induction motor, also of Canadian Westinghouse make. The coal-handling plant, together with the conveying system, was installed complete by Heyl & Patterson, Pittsburgh, Pa.

Coke Ovens

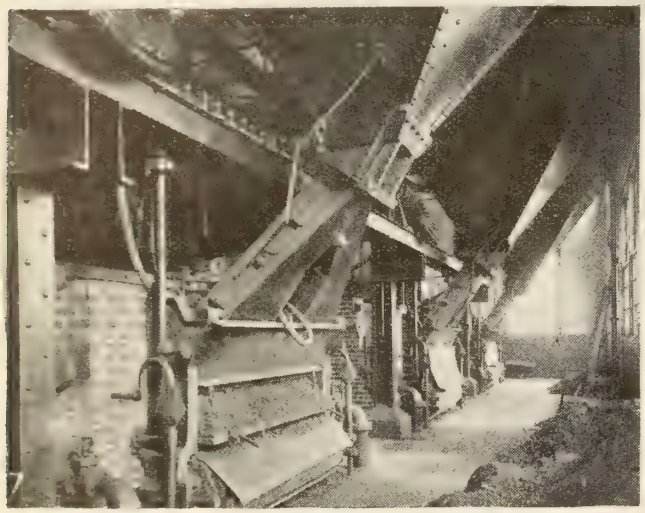
The Wilputte by-product coke ovens are arranged in two batteries placed end to end. Each battery consists of 40 separate ovens. Between each oven 28 flues are built into the side walls by means of which the ovens are heated by conduction through the brickwork. Below the ovens and flues proper, regenerative chambers are built in. These are filled with checkerwork and function similarily to those used with the open hearth. A cross-flue connects the tops of the vertical flues with whichever portion of the regenerator is on heat. The air necessary for the combustion of the gas employed passes through that side of the regenerator which is on blast and passes upwards into the twenty-eight vertical flues. At the bot-

tom of these it meets the incoming gas and combustion takes place.

A balanced draft system is employed, that is forced draft delivers the air to the regenerators and induced draft removes the products of combustion. The fans for the air supply are of Canadian Sirocco type and are steam-driven. Three are provided, two in constant use and one spare. The volume of air supplied is controlled from the chart room immediately above.

The induced draft apparatus is housed in a separate building and here three Canadian Sirocco fans are also provided, one of them spare as before. The products of combustion escape through two radial brick chimneys six feet by 75 ft. in height. These chimneys were installed by the M. W. Kellog Co., New York. The exhaust fans are steam-driven and the engines have 8 in. cylinders by 8 in. stroke.

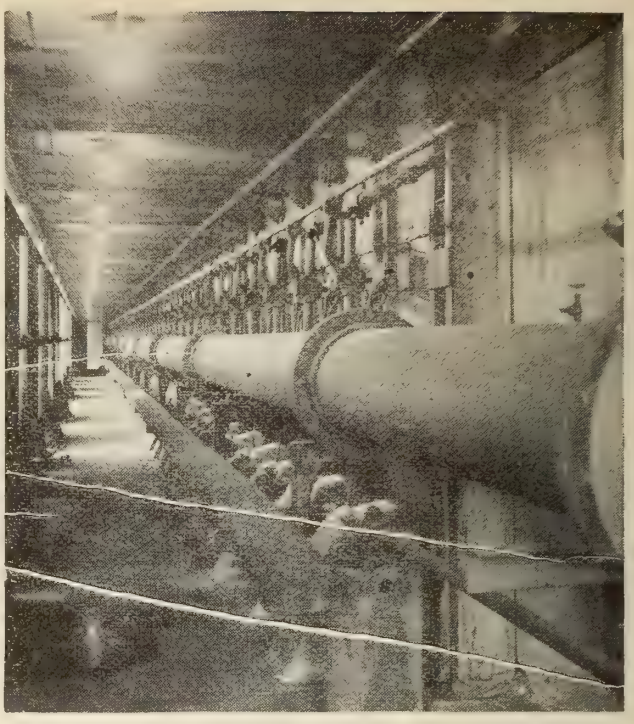
Ordinarily it has been customary on installations of this type to dispense with induced draft fans and to use 200 ft. chimneys for the securing of the necessary draft. It was thought, however, that better regulation and control



COXE STOKERS AND FEED CHUTES FOR COKE BREEZE.

could be secured with the equipment installed, and operation has confirmed this opinion.

The gas necessary for the maintaining of the proper temperature in the ovens is supplied by two sixteen-inch mains which are carried along the outside walls a few



ONE OF THE GAS MAINS ON THE COKE OVENS SHOWING THE RISERS AND VALVE CONTROL.

feet above ground level. From these gas mains risers are led off and into the flues. Each riser is equipped with a valve actuated by a rod running the full length of each battery and operated by a motor-driven controlling mechanism.

The air supply is also controlled by reversing valves, motor-operated, and at each half-hour period the flow of air through the regenerators is reversed.

Chart Room

Between the two batteries and over the fan room, a chart room is located. All recording instruments and controls are brought together in this room which provides a central point from which all operations can be directed.

The gas consumed in the heating of the ovens is here measured by two Venturi meters and the pressure on the gas main, the forced draft and induced draft pres-

THE PRIMARY COOLERS IN WHICH THE GAS IS COOLED AND IS FREED OF THE GREATER PART OF THE TAR AND AMMONIA LIQUOR.

sures are measured by three Bacharach pressure recording gauges for each battery.

Charging

The ovens are charged from above through four openings to each oven. A charging lorry with four bins travels the full length of the two batteries and receives its supply from the 1,400-ton bunker which is located overhead. Each hopper of the charging lorry holds sufficient coal for the charging of its portion of each oven. Between the ovens and immediately over each of the twenty-eight flues in the side-walls inspection holes are provided by means of which the condition of the brickwork and the combustion going on below can be observed.

When the charge in each oven is converted into coke it is removed by a pusher, almost human in its functions. The pusher travels the full length of the two batteries and is provided with three rams, one of which lifts the oven door off and draws it back out of the way, rocking it about a horizontal axis first to break the clay luting provided for gas tightness. The second ram, when this is accomplished, is advanced and pushes the coke through the door at the other end of the oven. The third ram is used after the doors have been placed back in position and when the fresh charge is placed. It is advanced and withdrawn several times through a small opening in the door and serves to level off the top of the charge.

The main pusher ram is driven by rack and pinion through two intermediate gear trains from a 75 h.p. motor of railway type. A magnetic brake is provided. The levelling ram is driven by a similar motor through a drum and cables. The door extractor is advanced from the cab and its further operation controlled by the door man on the platform. The coke pusher was supplied by Wellman-Seaver-Morgan, Cleveland.

The doors on the discharge side of the ovens are removed by a travelling extractor which is also provided with a coke chute to guide the red hot coke over the platform and into the quenching car below. The quenching car on receiving its load travels to a quenching station, shown in our first illustration, where the coke is wet down and later discharged onto an incline from which

VIEW OF BOILER ROOM SHOWING BREECHING, STEAM AND FEED LINES.

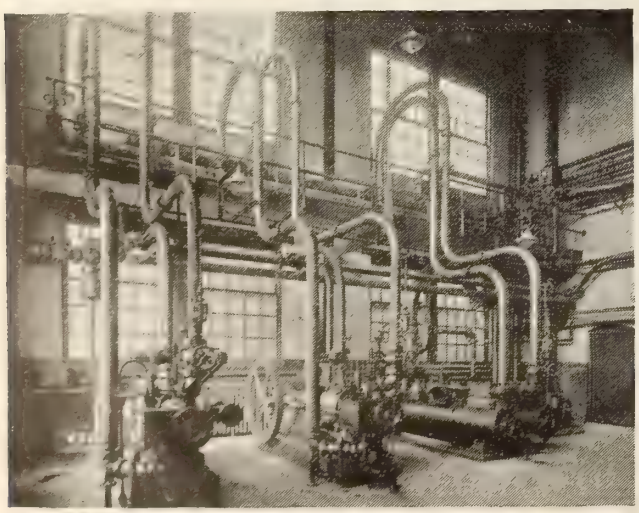
it makes its way by conveyor to the coke-handling plant.

The temperature at which the ovens are run has an important effect on the life of the brickwork; at this plant the side-wall temperature carried is 2,200° Fah. Silica brick are used of Harbison-Walker manufacture.

By-Product Plant

In the making of coke a number of valuable by-products are given off, gas which has a high calorific value, coal tar which finds use in the chemical industries and as a fuel, and ammonia compounds. All of these have considerable commercial value and when used in the steel mill or sold, materially lower the cost of the coke. A by-product plant is installed which purifies the gas and recovers the tar, ammonia content, and naphthalene carried over from the ovens.

Each oven is provided with an ascension pipe through which all volatile matters driven off during coking pass. Each pipe is equipped with a cap opening to atmosphere and a mushroom valve, and terminates in a common header. When charging, the gas driven off is allowed to escape until the operation is complete when the mushroom valve is opened and the gases allowed to pass into the header. The header running the full length of the two batteries has tar constantly circulating through it to catch any particles of free carbon carried over.



VIEW IN PUMP ROOM, BY-PRODUCT PLANT

From the header the gases pass over the pusher runway to the by-products plant and enter the condensers or primary coolers. These primary coolers, shown in one of our illustrations, are three in number, one of them spare. Each of them contain about 900 tubes through which water is constantly circulated on the counter-flow principle. The gases passing over the tubes have their temperature materially lowered and here most of the tar is thrown down, together with ammonia liquor and some naphthalene.

From the primary coolers the gas passes through the gas exhauster plant which provides the suction necessary to draw it over from the ovens. Three units are again provided here, two of them constantly in use and the third one as a spare. The blowers are built by the Connersville Blower Co., Connersville, Ind., and have a displacement of 51.7 cu. ft. per revolution. They are steam-driven, and Fleming engines are employed, made by the Harrisburg Foundry and Machine Works, Harrisburg, Pa. These units are controlled by electrical pressure regulators made by the Rateau Battu Smoot Co., New York. The speed is automatically varied according to amount of gas coming from the ovens and by this means a constant suction is maintained.

From the exhaustor the gas passes to the tar extractors which eliminate any tar fog which may remain. These extractors are three in number, one of them spare, and consist of vertical tanks which contain sheet steel bells perforated with 1-16 in. holes. The holes in successive cones are staggered and any particles of suspended tar are thus eliminated.

The gas is now free from tar but still contains considerable ammonia vapor. This is eliminated by the saturators through which the gas next passes. Three in number as before, these consist of large cast iron tanks lead-lined in which a 6 to 8 per cent. solution of sulphuric acid is maintained. The gas passing through this acid liquor gives up its ammonia content which unites with

the sulphuric acid to form ammonium sulphate. As this salt accumulates the solution becomes saturated and crystals of ammonium sulphate are thrown down. To effect their removal the principle of the air lift pump is adopted. A jet of air is blown into the bottom of a vertical discharge pipe and carries with it the crystals of sulphate together with some of the acid liquor. Flowing out of the saturator at the top, the mixture passes into lead lined settling trays where the ammonium sulphate falls to the bottom. It is then thrown into steam-driven, centrifugal separators where any remaining acid liquor is thrown off. The liquor is here recovered, and that from the ammonium sulphate is taken to the salt room where it is bagged and shipped to outside consumers.

Quite a romance might well be written about the by-product end of the coke industry. The coal tar is the starting point from which countless coal tar dyes and chemicals are made, and the nitrogen content of the coal is of great value to agriculture and other industries. Nitrogen compounds are essential to vegetable growth, and when these have been exhausted in the soil through intensive cultivation, artificial fertilizers are necessary.

Sulphuric acid has to be added to replace that used in the formation of the ammonium sulphate and it is found that about one pound of acid is required for each pound of sulphate made.

Ammonium sulphate can be used alone as a fertilizer, but more often reaches the farmer in the form of mixed fertilizers. It can be used with acid phosphate, potash salts, cotton seed meal, tankage and fish scraps. It is not subject to chemical action when thus incorporated into a mixed fertilizer and its freedom from free acid and moisture is also of advantage.

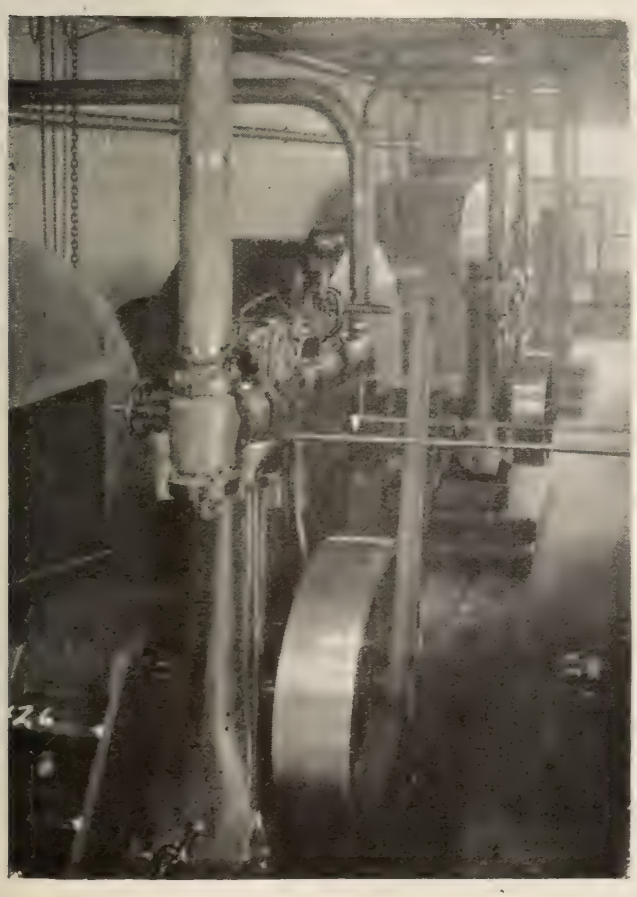
The gas, now free of tar and ammonia, finally passes through a washing tower where it meets a spray of water and is made ready for use. The water passing through this tower removes the naphthalene present in the gas and this is caught in settling basins for disposal.

MAIN ELECTRICAL SWITCHBOARD.

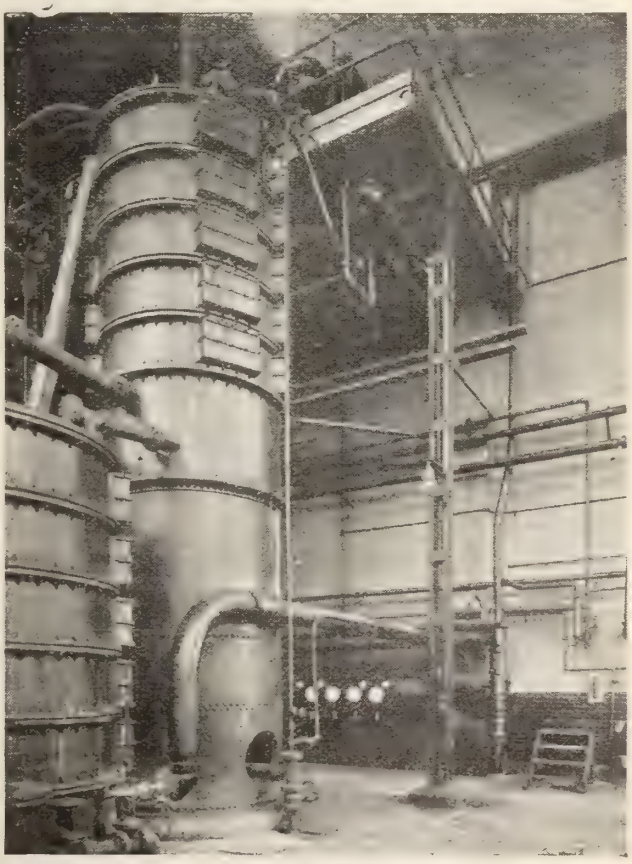
From the washer the gas goes to the gas holder and from this it is distributed to the open-hearths, the boiler room and to the coke ovens. That portion which goes to the open-hearth furnaces passes through an exhauster which raises its pressure to 5½ lb. The "Root" exhauster is driven by an R. 20x20 in. Ridgeway engine and has a capacity of 8,000,000 cu. ft. per 24 hours.

The operation of the by-product plant necessitates the handling of various kinds of liquids and a pump room is provided for the various pumps. Tar pumps of both centrifugal and duplex plunger type are provided for flushing the tar through the mains and headers. The centrifugal pump is of the Goulds single-stage type and has a capacity of 660 U.S. gallons against a 90 ft. head. It is driven by a Canadian Westinghouse 30 h.p. induction motor.

Two air compressors are also installed, made by the Chicago Pneumatic Tool Co.

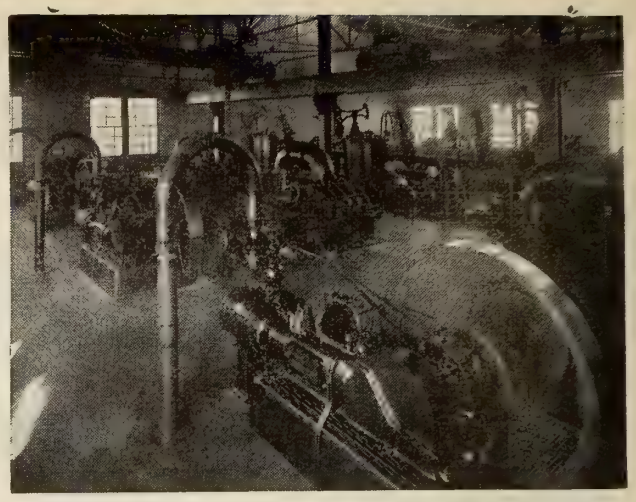


FAN ROOM FOR BY-PRODUCT OVENS



THE AMMONIA STILL IN WHICH THE AMMONIA LIQUOR GIVES UP ITS AMMONIA CONTENT.

COKE AFTER BEING QUENCHED.



THE EXHAUSTERS SHOWN HERE BRING THE GAS OVER FROM THE OVENS INTO THE BY-PRODUCT PLANT.

Operating Characteristics

Approximately 13 tons of coal are charged into each oven at a time. The coking time is 17½ hours and 108 ovens are charged per day, producing 900 tons of coke. Of this quantity the greater portion is required for the Steel Company's own blast furnaces, the remainder being disposed of to outside firms.

Each ton of coal as fired produces 11,000 cu. ft. of gas, 11 U.S. gallons of tar and 27 lb. ammonium sulphate. Forty per cent. of the gas is used in heating the ovens and the remainder is available for other plant purposes. The tar, together with most of the gas, is used in firing the open-hearth furnaces of which there are eleven. From each ton of coal three-quarters of a ton of coke are obtained.

Steam Generation

A considerable quantity of steam is used for the ammonia still and for the various engine-driven fans and exhausters. For the generation of this steam a boiler plant of 750 boiler horsepower has been erected.

Three Erie City double-drum water tube boilers are installed of 250 h.p. each. A steam pressure of 150 lb. is carried and the steam is superheated 100°.

In the making of coke considerable coke breeze or dust is made and this is used as a boiler fuel. The coke-handling plant screens all the coke and the fines are taken by belt conveyor to the boiler house. Here they undergo a further screening, chestnut size and over being eliminated, the remainder dropping into the bunkers in front of the boilers.

Coxe travelling grate stokers made by the Combustion Engineering Corporation, New York, are fitted to the boilers and are specially designed for the burning of the coke dust. This fuel is difficult to burn and in order to keep the ignition arches at the proper temperature it is necessary to burn gas as a supplementary fuel. Four two-inch gas pipes are led into the combustion chamber of the boiler setting above the grate and the gas passing through them is burned by excess air through the grates, no other air supply being needed. About 250,000 cu. ft of gas is burned per 24 hours in addition to the coke screenings.

The boilers are fitted with Diamond soot blowers made by the Diamond Specialty Co., Detroit and Windsor. All valves used in the boiler house are of Crane manufacture. Forced draft is supplied by a Canadian Sirocco fan provided with two engines, one of them spare. Pin and belt type clutches are provided for changing over from one engine to another.

The feedwater is heated in a Cochrane feedwater heater to 210° Fahr. Exhaust steam from the engines at 15 lb. back pressure is used for this purpose.

The feed pumps are in duplicate, two Canadian Fairbanks-Morse 10x6¼ duplex plunger pumps being installed.

The boiler house is some distance from the by-product plant and two six-inch steam lines are provided. These, for part of the distance, are carried overhead on structural frame work.

Construction

The coke ovens and other equipment including the by-product plant and boiler house were designed and installed by the Wilputte Coke Oven Corporation, 469 Fifth Ave., New York City, who also acted as their own general contractors. The silica brick necessary for ovens, etc., was supplied by the Harbison-Walker Co., Joliet, Ind., while the firebrick was furnished by The Evans and Howard Firebrick Co., St. Louis, Mo. All tanks and tankwork were supplied by the Jas. G. Hagey Co., Joliet, Ind. The coal and coke handling plant was furnished by Heyl & Patterson, Pittsburgh, while the Hamilton Bridge Co. furnished the structural steel. The two radial brick chimneys for the coke ovens and a similar but larger chimney for the boiler house were supplied and erected by the M. W. Kellog Co., New York City.

Methods of Storage and the Weathering of Coal

A Description of the Various Methods of Storing Coal and Their Characteristics, Together With a Discussion of the Factors Affecting Its Weather

By ROBERT JUNE, Mechanical Engineer

COAL storage is a subject which is being given more and more consideration each year by power plant operators. There are a number of reasons for this increased appreciation of the economical advantages of coal storage. Not the least of these is the danger of expensive shut-downs, due to strikes by miners or transportation workers.

There are execllent reasons why coal storage should be generally resorted to by power plant operators, by railroads, and by operators. We, of course, are concerned with the power plant, but because coal storage by railroads and mine operators offers some indirect advantages to the power plant operators, we may mention the reasons for such storage, briefly, without discussing the means.

As far as the railroads are concerned, a million dollars invested in coal storage facilities is equivalent to three million dollars invested in locomotives and cars, if purchased for coal moving purposes only. This is true because railroads are caled upon to move coal in large quantities only through three or four months of the year and if they have sufficient facilities to meet this peak load, there is a large portion of the year when the rolling stock will be idle. Another reason for coal storage by railroads is that it permits the railroad to haul its own coal at times when the equipment can best be spared for this purpose, so that the equipment need not be taken from earning service to do non-productive work.

Coal storage is important to the coal operator inasmuch as proper facilities for this purpose will enable him to regulate production and to maintain a uniform output at the mines. As matters stand, the average mine is operated approximately 170 days in the year. We would have fewer mines in operation, smaller overhead and more contented labor if all mines were equipped with coal storage so coal could be mined when cars were not immediately available. Inasmuch as lack of coal storage facilities by railroads and coal operators is one important factor in the present high cost of coal, it is important for every coal user to be familiar with the condition so he can use such influence as he possesses to remedy it.

Getting down now to the individual power plant, let us see what reasons may exist for the practice of storing coal in large quantities at, or near, the plant, and whether this practice is worth the expense involved. The general reasons for coal storage by the consumer are as follows:

1.—He can buy coal in quantities to better advantage at certain seasons of the year than at others, saving perhaps in this way anywhere from fifty cents to one dolar.

2.—The practice of storing coal by power plant operators would tend to equalize prices on different grades of coal. As matters stand, over production of certain grades at certain seasons of the year, and under production of certain grades at other seasons of the year, tends to penalize power plants using certain of these grades.

3.—Miners' and railroad strikes, and embargoes and delays will not effect plants where large quantities of coal are stored.

4.—The general practice of coal storage at the nation's power plants would help tremendously in solving the national situation by providing the miners steady work—(hence at "lower wages per ton of coal mined," and avoiding strikes, which in the end the consumer pays for.

The question as to whether coal should be stored in the individual plant will depend entirely upon the particular conditions obtaining in the case. It is out of the question, for instance, to store coal in or near a power plant situated in the business district of a large city. Here space is entirely too valuable for any such purposes. Unless the needs of the plant are extremely large and the source of supply somewhat uncertain, the city plant will also usually find it impracticable even to store coal in the outskirts of the city.

When we come to the small, medium, or large size power plant, which is so situated that coal can be stored conveniently in close proximity to the plant, on land of medium or low rental value, the case is quite different. Here everything points to the desirability of maintaining a storage system commensurate with the plant requirements. By purchasing and storing a year's supply of coal in the spring or early summer, the plant can normally effect such savings in purchase price alone as to pay for the cost of storage and handling several times over, to say nothing of the advantages of an assured supply of coal.

As to a choice of mechanical means for effecting coal storage, this will depend entirely upon the location of the plant and the storage pile, and the amount of coal to be handled. In previous articles we have discussed various types of coal-handling equipment, such as Mono-rail, Bucket, Chain and Flight Conveyors, etc., and it is not necessary to again describe this equipment. It should be noted, however, that in a great many cases, particularly where the quantity involved exceeds 10,000 tons, the locomotive crane, with grab bucket, appears to offer the ideal economic solution.

In planning coal storage for very small plants, it may be well to remember that coal can normally be hauled cheaper by wheel-barrow than by cart, up to a distance of 250 feet.

Choice of Storage Systems

In determining a storage system to be employed, most if not all of the following points will have to be taken into consideration:

1.—Character, size, location and value of available ground.

2.—Desired total storage capacity and amount of coal which may have to be loaded and unloaded per day.

3.—First cost of storage system and costs of maintenance and operation.

4.—Percentage of breakage which can be allowed in hauling coal.

5.—Length of time coal must be kept in storage.

6.—Effects, if any, of climate.

7.—Adequate available water supply.

8.—Means for rapid loading out of coal in case of fire.

In considering a storage plant from an economic point of view, it must be remembered that if the equipment is in operation very irregularly, that costs are consequently higher per ton because of the heavy fixed charges for interest and depreciation.

We have spoken of the locomotive crane as a generally cheap and satisfactory means of handling coal for storage in the usual boiler plant. The special advantage of the crane, of course, is that its functions need not necessarily be confined to the coal pile, as it can often be employed for other purposes about the plant. The locomotive crane is also adapted to quite a variety of storage systems, being particularly suited to various "circular" types of storage.

Where locomotive cranes are used with large circular systems the gauge of the track on which the crane runs is important. When possible, the gauge should be approximately as follows:

4′	8½″	for maximum swing of		30	feet
14′	6″	"	"	45	"
16′		"	"	60	"
20′		"	"	100	"

In planning large circular storage systems, the usual arrangement is one whereby the coal is discharged from railroad cars into a pit at a central point, which pit is also the centre of the circular track system on which the crane operates, the radius of the circular track being equal to the maximum swing of the crane. With such a system, the locomotive crane can pick up coal from the dumping pit when standing at any point of the circular track. By a swing

of the boom the coal can be deposited at any point inside or outside the circular track as far as the boom can reach. While it would be feasible to do so, it is not considered good practice to cover up crane tracks since it is very desirable to be able to operate the crane over the entire range of the storage pile in case of fire.

Characteristics of Different Coals When Stored

Some coals may be stored with greater safety than others. Danger from spontaneous combustion, however, is more apt to be present as a result of improper piling of coal than to the kind of coal stored. In storing bituminous coal the important consideration, as far as freedom from spontaneous combustion is concerned, is to see that fine coal and dust are not present. This would seem to preclude the storing of slack coal and run-of-mine, which are precisely the grades which many boiler plants wish to store. It may be said unreservedly that it does preclude the storing of this kind of coal in the open air as far as safety from fire is concerned. Where provision can be made to flood or to rapidly load the coal which has caught first, there is no special reason why run-of-mine and slack should not be stored.

Spontaneous combustion is principally due to oxidation taking place on the surface of the coal. With very fine and powdered coal there is an immensely greater surface presented for oxidation than with lump coal, consequently the danger of fires is very much greater.

If lump coal alone is stored, the danger of spontaneous combustion is practically eliminated. Coal which has gone over a 1½ in. screen, can be stored with little danger of fire. Coal with screenings removed has been kept in storage for many years without firing. Heating usually occurs within three months after coal has been stored. The tendency to spontaneous combustion decreases rapidly after that period. Where one has choice of coals for storage purposes, choice should be made of coal which is least friable, because less dust and slack will be produced in handling. Run-of-mine and slack coal have, at times, been stored without fire occurring by the exclusion of air from the interior of the pile. Such exclusion may be accomplished by a closely sealed wall built around the pile, or by close packing of the fine coal. However, securing of satisfactory results by such methods is both difficult and uncertain. Many men with experience in storing coal, believe that wet coal, or coal stored on a damp place, is peculiarly liable to spontaneous combustion.

Water Storage

If fires are absolutely to be prevented in the storing of run-of-mine or slack coal, the only satisfactory means is by underwater storage. Coal keeps indefinitely in good condition under water, losing none of its heating value and absorbing comparatively little moisture. Water storage possesses the further advantage in that coal does not deteriorate in physical properties, such as slacking. The cost of under-waterstorage is, of course, an important item, and may be so great as to preclude the use of this system. Where old quarries or abandoned clay pits are available for under-water storage, they may be at times adapted with smaller initial expense than would be required for other systems.

Methods of Piling Coal

To store coal successfully, the pile must be so arranged that the heat generated will not exceed the losses by radiation. Coal freshly mined has a special tendency to oxidation and heat. This property pertains to all varieties of coal, though it varies in intensity. The liability of spontaneous combustion occurring decreases with the period of time lapsing between the mining and storing of coal; hence, coal should be exposed to the air as long as possible before being placed in the pile.

To avoid spontaneous combustion, one of two principles should be observed: either the coal should be piled so that the air may circulate freely through it and thus carry off the heat due to oxidation, or the coal should be so closely packed that air cannot enter the pile and cause oxidation of the fine coal. Unless care is used in piling, stratification of the different sizes of coal in the pile may occur. This is a dangerous condition, since the open spaces between the coarse lumps of coal provide a passage through which air may enter and come in contact with the fine coal, thus giving it the opportunity to start combustion. In this connection, it is well to remark that it is not considered good practice to mix, indiscriminately, different kinds of coal in the storage pile, as experience has shown that this almost invariably leads to starting of fires.

It has further been noted that coal of high oxygen content seems to be especially susceptible to spontaneous combustion, a fact worth remembering when its storage is being considered.

There is no set rule as to the height of coal storage piles. Coal has been successfully stored in piles varying from six to sixty feet. Spontaneous combustion frequently occurs in very low piles. Low piles are preferable, since the coal is more fully exposed to the air, and in case of fire can more readily be loaded out. The principal disadvantage of high piles lies in the greater difficulty of moving the coal quickly in case of fires. The idea that high piles caused heating at the bottom is erroneous, since as many fires take place at the top of the pile as at the bottom, and as many near the outside as near the interior. Indeed, a depth of five or six feet seems to be a favorite point for fires to occur.

Ventilation

Ventilation by means of pipes in the pile has not proven a success in the United States. The expense of placing and removing the pipes is very high, and unless they are very close together, it is doubtful if they are of any special value other than for the purpose of thermometer shafts. In Canada, the Canadian Pacific Railway has very successfully ventilated its coal piles, entirely preventing spontaneous combustion. The method used is that of driving pointed iron rods, 1½ to 2 inches in diameter, vertically, down through the pile. After the rod reaches the bottom, a bell-shaped collar is slipped over it and forced down about six inches into the coal. The rod is then tapped to pack the coal around it and to loosen the rod, and then both collar and rod are withdrawn. As soon as this is done, a rough funnel of tar paper is put on the top of the bell-shaped collar to prevent small pieces of coal falling in, or being washed in by the rain. The walls of the hole maintain themselves without protection, ordinarily lasting many months. Holes are usually driven sixteen inches centre to centre. The cost, which is almost wholly labor, amounts to seven or eight cents a ton, at present prices.

Testing for Fire

Freshly stored coal should be carefully watched for evidences of heat. Fire will often be made evident by the presence of steam or by gaseous odors. However, it is unwise to depend solely upon visual evidence. Thermometer pipes should be driven at intervals into the pile. It is impossible to set any critical temperature applicable to all coals in varying storage conditions. One very safe rule is to be ready to remove the coal if the temperature reached 150 degrees F. After coal has been loaded out, it should be thoroughly cooled before being placed in storage.

In putting out fires, water is an effective agent only if it can be applied in sufficient quantities to entirely extinguish the blaze and to cool all of the heated matters. A small quantity of water is positively dangerous.

It is the practice of the Canadian Pacific Railway always to use water if the fire is a small one and particularly if it is detected at an incipient stage. The point of high temperature is located by driving test rods into the pile. A pit one or two feet deep, is then dug right over the centre of the trouble, and pointed rods or pipes are driven down into the heated matter. The pit is then filled with water from the hose and kept full, thus quenching the fire at its very centre. If the fire is a large one, the central pit is used, and in addition, a water curtain made by digging a ring ditch one or two feet deep, with a row of holes in its bottom. This ditch, like the centre pit, is kept full of water from the hose, and if there is any tendency for the fire to be driven downward from the centre it is put out by the water curtain. This method of putting out a fire is not cheap but it is very much quicker and much less costly, and results in much less loss of coal.

Effect of Storage

The heat value of fcoal is decreased very little by storage. Firemen, however are almost universally of the opini

hat storage coal burns less freely than reshly mined coal. This tendency may e overcome by keeping a thinner bed n the grate and by regulating the draft. he loss in heating values of coal in torage may be taken as one per cent. for he first week, with a very moderate increase after that period, so that at the nd of a year the total loss in the aver- ge case will not exceed three per cent.

In conclusion, safety in the storage of oal depends upon a very careful and horough consideration of methods and lose attention to details. Remember hat you will almost invariably have angerous fires if you attempt to simply ile up coal without taking thought of our methods and of your means of ghting spontaneous combustion, should t occur.

HE BIRTH AND DEVELOPMENT OF THE BAROMETER AND ITS USE

There is probably no instrument to which the progress of modern weather orecasting owes so much as the baroeter, the measure of the pressure of he atmosphere.

The word is derived from the two Greek words, baros—weight, and metron —measure.

The story told in connection with its invention" was that some Florentine workmen building a well were unable to aise the water much over 2 feet, and vent to the scientist Galileo to inquire he cause. The rise of water in a pump had been attributed to nature's abhorence of a vacuum. He remarked upon this hat it was evident that this abhorrence lid not extend beyond about 32 feet.

Galileo had a pupil, Torricelli, and of ll those who went to him at the Uniersity for education, he probably hought more of and extended more riendship to Torricelli than to any of he others.

Some time after Galileo's death, Torrielli considered that this water column vas supported by the pressure of the xternal air upon its surface, this forcng the fluid up to a height varying with he pressure and the density of the matter raised.

He then considered experimenting with iquids, the density of which should be eavier than water

Mercury was ultimately selected, its lensity being thirteen and a half times s great as water at the same temperature.

After this the famous experiment tarted. He took a glass tube which was losed at one end, and filled it with mercury. This he inverted into another vessel, also filled with mercury. The mercury in the tube fell somewhat, part of t passing into the vessel and on measuring the distance between the level of the nercury in the tube and the level of the nercury in the vessel, he found it to be 30 inches. Here was the first barometer of mercurial type. The well had been reproduced on a table with a glass tube and a glass vessel, but thirteen and a half times smaller than the original.

As the mercury in the tube fell, it, of course, left a vacuum, and to-day that is known as the Torricellian vacuum. It is a nearly perfect vacuum and contains only a trace of mercury vapor.

In moving this "apparatus" about Torricelli found the height of the column varied.

Pascal, a teacher of geometry, was consulted and suggested that change was due to the air being different in weight in different places. This theory was not altogether proved, but it was found that when the apparatus was taken up heights, the column became affected.

It was taken to an extinct volcano in the Auvergne region of France, and the level of the mercury fell to about 25 inches in contrast to its level of 30 inches when this party of "discoverers" left Clermont.

The assumption immediately was that the smaller amount of air above, supported a shorter column, or in other words the weight of the mercury in the tube could not be held up by the pressure of the mercury in the vessel. This was correct.

Refinements in this first crude instrument produces the standard mercury barometer of to-day.

The earliest known form of which was put to real scientific use can be seen in the Academia del Cimento. It consists of an upright glass tube graduated along its length, the end being fitted into an almost closed "Cistern" containing the mercury.

A glycerine barometer (S. G. I. 26) is on exhibition at the Geological Museum in London. On account of its low specific gravity compared to mercury, it gives a magnified reading of pressure changes and the errors due to vapor pressure are much less, or quite inappreciable compared to barometers made with water for the working member. Water barometers are rare nowadays, but they have been constructed. When the column in a mercurial barometer moves one inch, the column in the water barometer will move 13.6 inches for the same amount of change in pressure.

The "Aneroid" barometer, so called because it is constructed "wholly of solids," has taken the place of the cumbersome mercurial instrument for many purposes to-day.

Mercurial instruments are subject to many corrections before a true reading of atmospheric presure can be taken; whereas with a well and sensitively constructed aneroid, providing it is compensated for temperature, readings can be read straight off the circular dial.

The sun is the standard of time, but we have watches and clocks (high grade) which run accurately and are less expensive than a sextant which would be a necessary instrument to us if we depended upon accurate sun time. Aneroid barometers are rapidly taking the place of mercurial instruments, but the mercurial will ALWAYS remain the standard, the portable and sensitive aneroid will need checking occasionally (once every year or so) in exactly the same manner as our clocks need setting.

The figures put upon the faces or dials of barometers represent the pressure of the air at the place and at the time of observation.

When the hand points between 29 and 30, the reading is expressed at 29.5 inches, for it will be noticed that the dials are divided into tenths between the inch spaces and sometimes these tenths are divided again into tenths making hundredths of the whole, but the degree of the dividing depends on the ability of the instruments to give a delicate reading.

The change in the pressure of the air brings changes in our weather, so reading the barometer dial is in reality feeling the pulse of the air.

The sun is directly responsible for all our weather changes. The world, the land, the atmosphere and the ocean are his servants—his great "distilling apparatus" as it has often been described. The warm south seas are the boilers, the northern and southern regions of cold the condensers, and the sun, the furnace.

This huge and complete pumping engine pumps up and showers down water. The atmosphere does not and cannot work alone—it works in company with the land and ocean under the sun's control.

The steadily heated tropical oceans send into the air streams of vapor, which as they rise become colder. They do not chill merely because the lessened weight of the air causes an expansion, and in this act of expansion or stretching, a certain amount of heat is given out.

The air growing colder becomes virtually damper because it is more nearly saturated—more nearly obliged to part with some of its hidden vapor. When it reaches the actual saturation point and does not lose moisture, the result is a fall of rain. The torrents peculiar to the "Calm Belt" receive a good amount of this precipitation, but the air still rising reaches that level where the anti-trade winds flow to the north and south and become carried in those directions.

In all these operations the real working power is the sun. The atmosphere without him would be like a steam engine without furnace fires—a powerful machine, but powerless to act.

Lifting these hundreds and thousands of tons of water—calmly, gently, noiselessly, with no sign of effort or strain, is done hourly by the sun through the obedient air.

Out of the ocean into the air; out of the air into the clouds; out of the clouds into the rivers; out of the rivers into the ocean, and so on through this endless circular chain.

P. R. JAMESON in the "TYCOS" House Organ.

The Possibilities of Pulverized Fuel

The Commission of Conservation Has Paid Considerable Attention to the Possibilities of Utilizing Canada's Low Grade Fuels and the Report on Pulverized Fuel, of Which This is an Abstract, Points Out One Successful Method

By WILLIAM J. DICK, M.Sc.

NEARLY a century ago pulverized coal as a fuel was experimented with, but its application to industrial purposes really commenced in 1895, when used in connection with the burning of cement. Its comparatively slow development was due largely to the fact that the advantages of thorough drying and fine grinding were not fully recognized. It was not until the pressing demands of the cement industry for a low-priced fuel of high efficiency became imperative that pulverized coal was found almost ideal. In this industry it is essential to grind cheaply the cement materials to a high degree of fineness so that the pulverizing of coal fell naturally into the hands of men able to powder cheaply, and to the same consistency, a material much less resistant than cement rock of clinker. The next general application of this fuel was in certain metallurgical processes, such as a source of heat for simple furnaces, where excessive temperatures were not required and where the ash deposits were either continuously removed with the heated material or could readily settle on the hearth and be withdrawn.

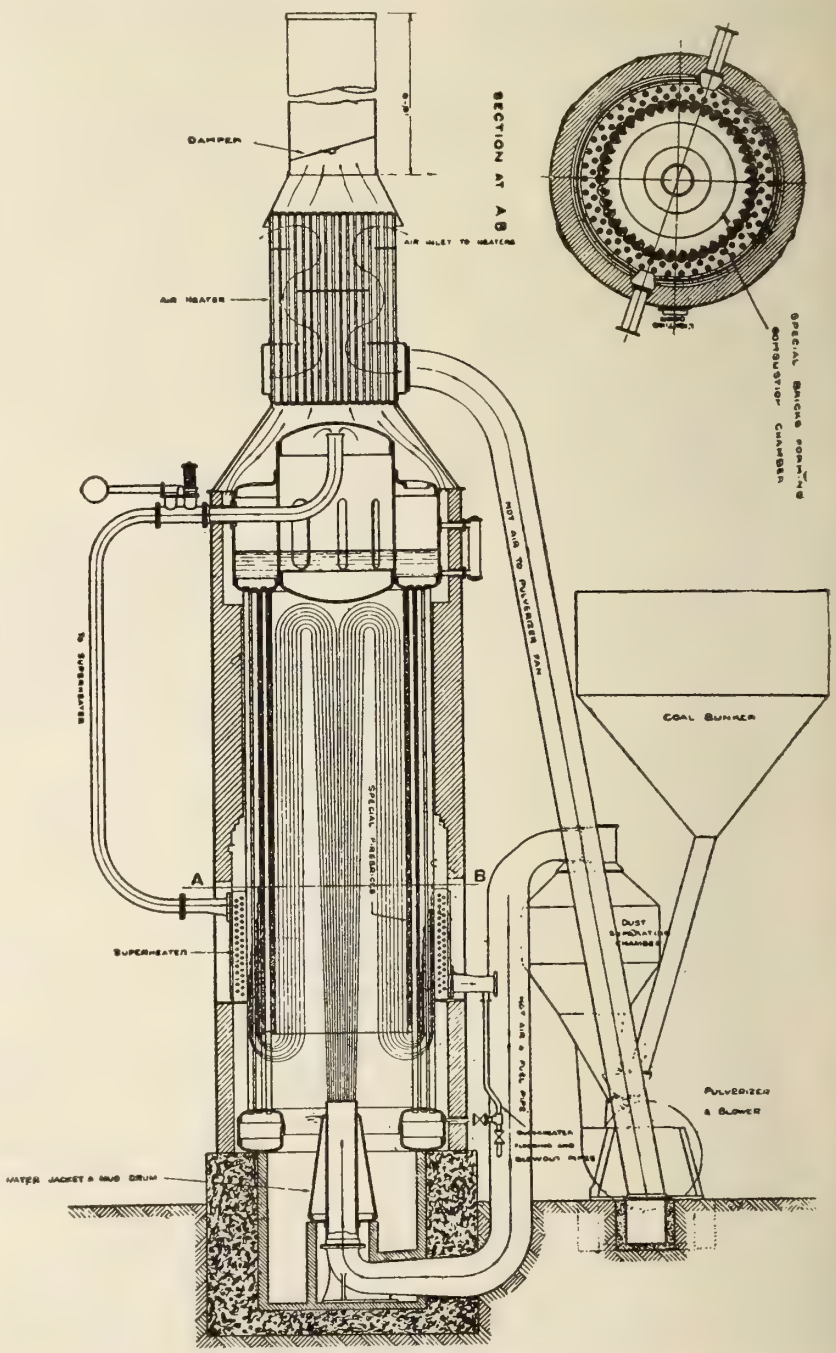
About sixteen years ago, the Manhattan Elevated railroad experimented with pulverized coal as a fuel on one of its locomotives. The equipment consisted of a combined pulverizer, blower and steam turbine situated on the locomotive. It is understood that, as the coal was not ground sufficiently fine and because certain mechanical details were not provided for, this method of burning coal was not successful.

During the last few years the Swedish Government and Swedish Boiler Society have carried on tests, using pulverized peat as a fuel on locomotives and stationary boilers, which have resulted in the successful use of this class of fuel.

In 1914, the New York Central railroad placed in operation a locomotive, of the ten-wheel type, having a tractive power of 31,000 pounds. This was the first locomotive of any size to be equipped and successfully operated for burning pulverized coal in suspension. Since then a similar application was made to an Atlantic-type locomotive of the Chicago and Northwestern railroad. Early in 1917 the Delaware and Hudson railroad installed the first complete commercial plant for supplying pulverized coal to one of its locomotives operating in regular train service.

In 1906 coal dust was experimented with in connection with reverberatory copper smelting at the Highland Bay smelter. While these experiments did not lead to its final adoption at this smelter, the results obtained showed very clearly that increased tonnage, with decreased fuel consumption, could be attained, and that such difficulties as were encountered were largely mechancial and presumably removable. In 1909 the use of pulverized coal as a fuel was investigated by Messrs. David H. Browne and Geo. E. Silvester, of the Canadian Copper Co., and, as a result, it was decided to instal coal-dust firing in connection with the reverberatory smelting of copper-nickel ore and flue-dust at their smelter Copper Cliff, Ont. Construction of the plant was begun in 1910 and completed in 1911. After investigating the work of the coal-dust fired reverberatories of the Canadian Copper Co., the management of the Washoe Reduction Works, Anaconda, Mont., decided to experiment with and ascertain the advantages of using coal-dust as a fuel in their reverberatories. In 1914 a reverberatory furnace was remodelled to use pulverized coal as a fuel, and the results obtained showed a decided saving in cost of smelting, as compared to grate-firing with lump coal.

In 1912 the American Iron and Steel Manufacturing Co. had carried its experi-



SECTIONAL VIEW OF BETTING BOILER.

ments to a point where it was ready to publish statements of the successful uses of this fuel. In their plant at Lebanon, Pa., pulverized coal was used as fuel for puddling furnaces and small reheating furnaces for nut, bolt and spike bars, and in large furnaces for continuous billet-heating and open-hearth melting.

During the last few years pulverized coal has also been successfully used in stationary boilers. In 1913 the Dominion Coal Co. installed Bettington boilers, burning pulverized coal, in connection with its power plant at New Waterford, N.S. This was the first installation of its kind in North America.

Pulverized Fuel in Boiler Plants

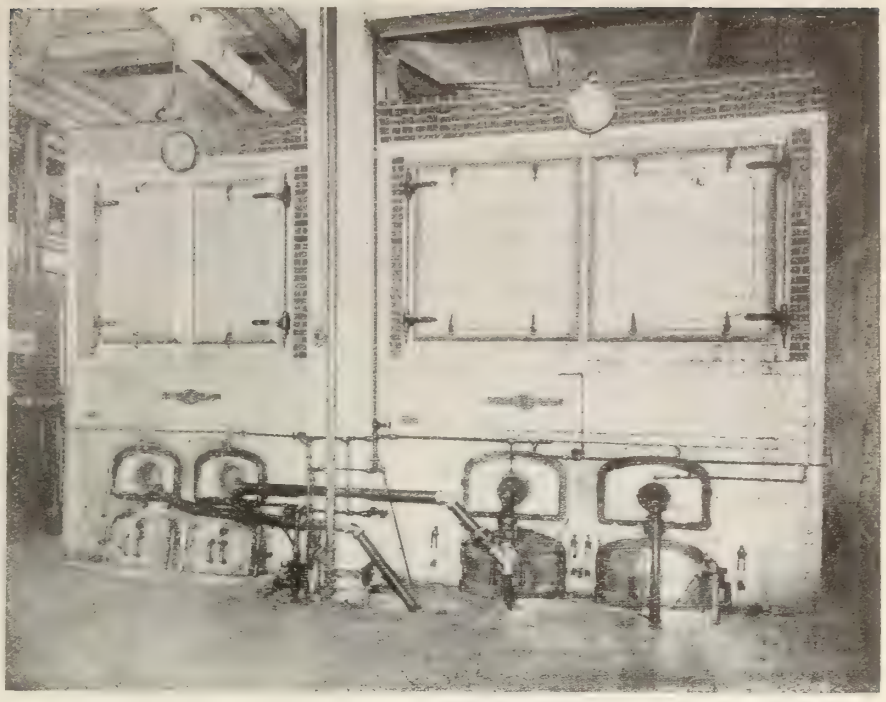
The development of the use of pulverized fuel in stationary boiler practice is of much later occurrence than its use as a metallurgical fuel. The early experimenters did not appreciate the necessity of fine grinding, nor the influence of furnace design upon the temperature of the resulting gases, consequently trouble was experienced through the action of the high temperature flame upon the brickwork. The blow-pipe effect of the high-velocity jet tended to melt the brickwork. A layer of slag, formed by the fusing of ash and brickwork, accumulated in the bottom of the combustion chamber and discouraged those who depended upon this fuel for continuous service. Difficulty was also encountered in the minute particles of liquid slag being carried in suspension and deposited upon the tube-sheet or water-tubes of the boiler, therefore interfering with its operation.

The knowledge gained recently, both in experimental work and by experience in equipped plants, has shown that these difficulties can be, and have been, overcome. The economy secured by the use of pulverized fuel in stationary boilers, instead of hand-fired coal, is not as great, in comparison as that derived from its use in locomotives. This is due, largely, to the fact that, it is possible to equip stationary plants with the best mechanical stokers. There is an advantage of two or three per cent. in combustion efficiency in favor of pulverized coal, but this is offset by the additional cost of fuel preparation. While the above comparison is made from the standpoint of efficiency, and where almost similar coal is used, there are many localities, especially in Northern Ontario and portions of Manitoba, Saskatchewan and Alberta, where pulverized peat or pulverized coal could be used to decided economic advantage instead of higher-priced imported coal.

Bettington Boiler

Boiler Plants—This combined boiler and pulverizing plant is the result of a long and expensive series of experiments, commenced in South Africa, continued and first patented in United States, and finally completed and commercially exploited in Great Britain. A summary of the difficulties encountered in applying pulverized fuel to steam-boiler practice is presented as follows in the catalogue published in the interest of this boiler:

(1) The difficulty of maintaining continuous and steady ignition; a difficulty only met by maintaining a uniform and very high temperature in the furnace.



500 HORSEPOWER PLANT USING PULVERIZED FUEL IN THE L. C. SMITH BLDG., SEATTLE, WASH.

(2) The failure to find an economical material to stand the destructive temperature necessary in the furnace as hitherto arranged for boiler firing.
(3) The difficulty of producing a continuously homogeneous mixture with varying grades of coal, sometimes very wet, and high in ash.
(4) The difficulty of maintaining a homogeneous mixture of fuel-dust and air during the full period required for complete combustion; the tendency of the larger solid particles being to concentrate in certain lines of direction; a difficulty met in part by extremely fine pulverization of the fuel.
(5) Difficulty of handling the molten ash, which from the required type of, furnace and temperature, must usually form solid deposits of slag.

The essential features of this type of boiler are:—

(1) Pulverizer and blower.
(2) Dust-separator chamber.
(3) Water-cooled nozzle or tuyere.
(4) Vertical water-tube boiler.
(5) Air heater.

The coal is fed automatically to the pulverizer, which acts also as a blower. The air, before being drawn into the pulverizer, is heated by means of an air-heater placed in the path of the waste gases from the boiler. By pre-heating the air, coals containing up to 15 per cent. moisture can easily be disintegrated and burned.

The coal, after being disintegrated, is delivered into the dust-separating chamber, the fines passing direct to the fuel nozzle and the coarser particles returning by gravity to the pulverizer for further reduction.

The fine coal delivered at the nozzle, and which, practically speaking, may be considered as a gas, is ignited and burns in the combustion chamber of the boiler. The heated gases pass from the combustion chamber up between the water tubes, through the economizer and air-heater, to the stack. The boiler consists of top and bottom headers, with solid drawn-steel tubes connecting them. Special bricks in combination with the innermost circle of tubes form the wall of the combustion chamber. No binding material is employed for these special bricks. The combustible matter in the fuel is said to be consumed and the residue is an irreducible vitreous slag. The slag solidifies at a relatively high temperature, and soon chokes up and hermetically seals all crevices, cementing the lining into one solid piece. The bulk of the slag falls into the ash-pit below in the form of small globules which are easily removed, the quantity being very small in comparison to the ashes from an ordinary hand-fired boiler. The steam, before passing to the turbines, is superheated by means of pipes spirally wound around the boiler tubes.

For this type of boiler, the manufacturer claims the following advantages:

(1) The boiler will give an efficiency not given by any other boiler on the market.
(2) They can be fired at any desired rate by adjusting the feed of the pulverizer.
(3) They are easily cleaned.
(4) After being closed down for a time, full steam can be generated quickly.

In 1913 the Dominion Coal Co. installed in their plant at New Waterford, N.S., three Bettington boilers, each having a normal evaporation, from and at 212 degrees Fahr., of 20,000 pounds per hour. They are fired with slack coal which could not be economically used to generate power in the ordinary boiler. This plant was the first of its kind to be installed in America. Other users of this boiler are the British Admiralty, Johannesburg Municipal Power Station, Clifton and Kersley Coal Co., British Oil and Cake Mills, of London, Hull and Manchester, Erith Urban District Council, De beers Diamond Mines, Donisthorpe and Co., Jupiter Gold Mining Co., Warren Hill Syndicate, Ltd., Crown Mines, Ltd., Bantjes Consolidated Gold Mines, Ltd., all of which,

it is claimed, are securing the greatest satisfaction.

The boilers are built in five standard sizes, with evaporations from 6,000 to 40,000 pounds per hour, at normal evaporation from and at 212 degrees Fahr., as follows: No. 1, 6,000; No. 1*a*, 8,000; No. 2, 12,000; No. 2*a*, 20,000; No. 3, 40,000 pounds per hour.

The following are the results of tests on this boiler, as outlined in the catalogue before mentioned:

Coal used	C.R.C. nuts	Dant		South African		Duff	Welsh anthracite duff
		Clifton Kersley	Ellesmere	Partings	Pickings		
Analysis (on dry coal)—							
Ash	22.18	23.00	21.12	22.58	21.30	19.92	12.64
Volatile matter	25.97	20.00	26.46	27.38	27.68	22.94	11.66
Sulphur	.....	.....	3.13	0.85	0.95	0.76	0.99
Fixed carbon	51.85	57.00	52.42	50.04	51.02	57.14	75.70
Calorific value on dry coal (B. t. u.)	8,710	10,700	11,250	10,098	10,494	11,088	12,276
Calorific value on dry coal (B. t. u.), expressed as pounds of water, evaporated from and at 212 deg. Fahr.	9.01	11.08	11.65	10.45	10.86	11.48	12.71
Absolute steam pressure, pounds per sq. in.	140	164.5	164.8	152.3	152.15	130.45	151.1
Average temp. gases escaping from boiler, deg. Fahr.	514	592.7	658.8	558.3	587.5	603.7	560.3
Average temp. feed water deg. Fahr.	76.6	.....	56.6	56.0	56.0	56.0	57.2
Pounds dry coal fired per hour	1,084	1,020	1,179.2	1,183.3	1,347.8	1,183.5	1,242.2
Actual water fed per hour, pounds	6,380	6,550	7,984	7,348.1	8,803.6	8,471.4	9,217
Equi. water evap. per hour from and at 212 deg. Fahr.	8,495	8,476.8	10,290.4	9,437.2	11,321.4	10,909.5	11,776.4
Pounds water per pound coal, actual	5.37	6.418	6.635	6.111	6.401	6.986	7.36
Pounds water per pound coal, actual from and at 252 deg. Fahr.	7.15	8.309	8.726	7.975	8.40	9.218	9.48
Thermal efficiency, based on coal	79.3	75.0	74.9	76.31	77.35	80.30	74.59
Percentage of moisture in coal during test	8.66	15.6	2.00	1.6	2.00	2.4	0.8

R. H. Fernalde states that an examination of the installation at the works of the agents of the Bettington boiler "gave an excellent impression of the operations of the pulverizing equipment, with its freedom from floating dust. Unfortunately, no examination of the effect of fusing of the ash could be made, as the boiler was under test and access to its interior was out of the question. The company claimed that, after years of experimental work with special fire bricks, it has developed that the method of inclosing the water tubes of the boiler practically amounts to water-cooling the brick. It is, therefore, possible to dispense with special, expensive, high-grade brick for this purpose and to use common fire-brick.

"This installation consists of a boiler of slightly over 2,600 sq. ft. of heating surface, which has an evaporative capacity of 14,000 to 22,000 pounds of water per hour. The power required for pulverizing and feeding the fuel is stated to be about 3 per cent. of the boiler capacity.

"No definite information regarding depreciation and maintenace was available, but by some these items are regarded as excessive.

The manager of a steel plant in Wales reported that he was using two of these boilers. He had installed two boilers rated to evaporate 20,000 pounds of water each per hour. He stated that he was using refuse coal containing 25 to 27 per cent. ash —a mixture of colliery dust and coke dust. The boilers had been installed only about two weeks and had consequently not been thoroughly tried out. Tests of the boilers showed an efficiency of 75 per cent., and the indications were that the boilers would be entirely successful."

The following is the result of a comparative test of a large marine-type Babcock and Wilcox boiler and a Bettington boiler of nearly the same size. The latter was the first of its type, and is no doubt capable of some improvement as the result of the experience gained. It will be seen, however, that it compared well with its older rival. The figures are as follows:

Item	Bettington tests	Babcock and Wilcox tests
Date of test	June 26, 1913	June 27, 1913
Duration of test	9.8 hours	10 hours.
Gauge pressure	173.7 lbs. per sq. in	161.9 lbs. per sq. in.
Feed temperature	65.5 deg. Fahr.	64.7 deg. Fahr.
Steam temperature	510.3 deg. Fahr.	546 deg. Fahr.
Water evaporated per hour	31,561 lbs.	29,370 lbs.
Coal consumed per hour (no allowance made for carbon value of ashes)	4,477 lbs.	4,183 lbs.

Item	Bettington tests	Babcock and Wilcox tests
Pounds of water evaporated per 1 pound coal (as fired)	7.050 lbs.	7.014 lbs.
Evaporative equivalent from and at 212 deg. Fahr. (as fired)	9.049 lbs.	9.140 lbs.
Evaporative equivalent from and at 212 deg. Fahr. (dry)	9.464 lbs.	9.868 lbs.
Efficiency on gross calorific value	78.6 p.c.	77.4 p.c.
Percentage auxiliary power	3.8 p.c.	1.0 p.c.
Net efficiency on gross calorific value	75.6 p.c.	76.6 p.c.
Efficiency on net calorific value	81.4 p.c.	80.0 p.c.
Net efficiency on net calorific value	78.3 p.c.	79.1 p.c.

Pacific Coast Coal Company, Seattle, Washington

This company was the pioneer in the development of the use of pulverized fuel on the Pacific coast, and, to-day, the industry has reached a high stage of development, particularly in connection with the use of pulverized coal for boiler plants, and for power and heating purposes.

This company owns and operates the following mines in the state of Washington: Black Diamond, Newcastle mine, and the Burnett or South Prairie mine, all of which are in the vicinity of Seattle.

DELIVERING PULVERIZED FUEL BY MOTOR TRUCK.

The following are analyses of these coals:

Black Diamond Mine

(As Mined)

Moisture	2.05	per cent.

Sulphur	1.29	"
B.T.U.	12,169	

This company owns and operates two pulverized coal plants—one at the Newcastle mine and the other at Black Diamond mine.

Newcastle Plant—This plant has a capacity of five tons per hour, and consists of one Ruggles-Coles dryer and one 46-inch Fuller mill. The pulverized coal is used in the mine power-plant, and for shipment to Seattle.

Black Diamond Plant—This plant has a capacity of five tons per hour, and consists of one Ruggles-Coles dryer, and one Raymond mill. The pulverized coal is used in the mine power-plant and for shipment to Seattle.

The pulverized coal is shipped to Seattle in tank cars, and distributed by tank motor trucks. This company has built up a commercial business of about 30 tons per day, and the following buildings have converted their boilers from oil-burners to the use of pulverized fuel: The L. C. Smith building (42 stories), Pacific block, Broadway high school, New Richmond hotel, Seattle natatorium (Crystal Pool), and Independent laundry. The price of pulverized fuel, delivered, is $7.75 per ton, a saving over fuel oil, which formerly cost $2 per bbl. of 42 gals.

FIRE SMALL QUANTITIES AT FREQUENT INTERVALS

When soft coal is placed on a hot fire a considerable quantity of gas commonly called violatile matter is driven off rapidly. This process which is known as distillation takes place whether or not air be present. However, to secure the entire heat of the volatile matter, these gases must be completely burned before passing out of the combustion chamber. Most coals used in this state have a high percentage of volatile matter. In the case of some coals the volatile matter represents over 40 per cent of the heating value.

Since distillation takes place in the first few minutes after firing, and the rate of flow of air through the fuel bed is practically constant, extra air must be admitted above the fire during this time, in order to secure complete combustion. It is usually found necessary to admit this extra amount of air required, either through the damper openings in the fire doors or by leaving the fire doors open slightly for a few minutes immediatey after firing.

As the amount of gas given off depends entirely upon the amount of fresh fuel, small amounts should be fired at frequent intervals to maintain as nearly as possible the proper proportions between fuel and air supply. The fire door dampers should be opened, or the doors cracked slightly for 2 or 3 minutes after firing. The fire doors should be closed as soon as the gas is burned or the furnace will be cooled off and heat wasted.

The Wisdom of Boiler Inspection

ON July 26 last a boiler exploded at a cheese factory in Pittsburgh township, near Kingston. An investigation brought out the fact that it had never been properly inspected since installation, and no doubt the failure could have been prevented if this measure of precaution had been observed. The explosion, in addition to much material damage, caused the loss of a life, and this fatality has recently been the cause of a decision handed down by the Supreme Court. A jury has awarded $1,000 damages to the father of the deceased, since the death was due to the negligence of the defendant in having installed a boiler which had not been officially inspected.

This decision opens up an interesting line of thought, and would imply a material extension of the owner's responsibility. While boiler inspection is not in every case a preventive of explosions, it is recognized as being a sensible and indeed a necessary precaution, and when it is not done, as in the present case, the jury would be perfectly right in assuming contributory negligence.

Do Fashions Change in Engineering?

LUBRICATION experts have told us for a long time that acid of any kind in lubricating oils was dangerous and should never be tolerated. Corrosion troubles, under certain conditions, and other disadvantages were supposed to result from any lubricant not almost chemically free from either mineral or fatty acids.

Along came two investigators who, in a paper before the Society of Chemical Industry, claim that this is all wrong, and that by adding a small proportion of fatty acids the lubricating qualities of the oil are vastly improved.

The authors use the expression "germ process" to describe the oil made by using one or more fatty or other acids with one or more mineral oils, because the world has been taught for generations to look upon acid as the deadliest enemy to good and safe lubrication. Had they not used guile of some kind to cover the leopard's spots, "peaceful penetration" had been almost impossible.

The word germ has been used in this sense since, while the fatty acid germ is not alive in the sense that germs are, it is very active and so, it is claimed, affects the properties of the oil in a profound manner. Compounded oils have, of course, long been known, and many specifications call for so much mineral oil and so much of some particular vegetable or animal oil. Formerly all specifications and other requirements strictly limited the amount of free acid in compounded oils to a very small amount, and in mineral oils to none at all.

These investigators have upset all this, and instead of vegetable or animal oils and fats, they add fatty acids to mineral oil and eliminate the organic oil. The fatty acid produces an oil with varying properties as desired and it is quite possible to produce an oil which will work well in the crank-case of forced lubrication engines without emulsification.

For a good, heavy marine engine oil it has always been considered necessary, and is so to-day, to use from 10 to 25 per cent. of a thickened or blown oil—as a rule, thickened rape oil. This gives great viscosity, also very good "latherng" properties to the oil. A marine engineer must see the oil "lather" well, or it is no use.

The standard specification for marine bearing oil for one of the semi-Government departments in Great Britain is a compound of about 20 per cent. "of fatty oil"; but the total fatty acid content must not exceed 1 per cent. This department was considered most conservative, yet germ-process-marine-engine oil is doing, and has done for about eighteen months the same work for which a 20 per cent. compound oil was previously considered essential.

In the power plant and on board ship it is quite possible that this new lubricant may affect considerable changes.

An Error in Topography

A WRITER in an American contemporary, speaking of a new 15,000-ton steamer now building for the White Star-Dominion Line, says that she is to be named the "Calgary," after the Canadian province in which the Prince of Wales owns a ranch. This reminds us of an old lady, who, after listening all evening to a traveller's tales of the Orient, remarked, "Yes, China must be a wonderful city."

"Why Do the People Rage and the Heathen Imagine a Vain Thing?"

The Editor *The Engineer*,
London, England.

SIR:—It was stated in *The Times* for January 13th that a professor in the United States has invented a rocket which is capable of passing right through the atmosphere. The question arises in my mind as to whether there is not a certain amount of risk about experiments of this kind which it is undesirable to run.

Professor Jeans, in his book, "The Dynamical Theory of Gases," states, it seems with good ground, that "the proportion of a light gas, however rare at the bottom, must necessarily exceed that of all heavier gases after a sufficient height," and that consequently at very remote altitudes there is a large proportion of hydrogen. In the absence of sufficient oxygen, it, of course, would not burn, but it is more than possible that an explosive belt may occur, which the new rocket would ignite, if it ever got there. This operation might merely lead to an unprecedented display of the nature of an aurora; on the other hand, it might bring about the end of the world, so far as we are concerned.

It may be objected that if this was likely to happen, the effect would have been produced long ago by meteoric agency. The answer to this objection is that meteors derive their incandescence from the friction of the atmosphere, which is practically non-existent where the latter is so highly attenuated as it would necessarily be at the levels under consideration. In other words, all their heat is generated when nearing home.

Perhaps some of your other readers will say what they think. If my view is correct, an authoritative protest should be sent to the Smithsonian Institute at Washington.—C.F.O.M.

The Good Old Styles

THERE'S not much end to ways and styles that folks is usin' now, and some is awful common like and lowly in the brow. While others aim at higher planes, a most delightful thing, and of them now let's string our lyre and raise a voice and sing.

There's lots of folks wear dinky hats what squat upon their head, in temperatures that make the snout turn most alarmin' red—they walk along the streets they do, in manner quiet and smug, a hangin' to their nose a spell and wackin' at their lug.

And on their hands they wear, they do, gloves of some dainty hue, what let their fists become at onct both numb and freezin' blue.

Upon their feet they grow silk socks, yes pleasant things in June, but ugly things, my lad, by heck, when frost hangs on the moon.

And there they strut both to and fro, rigged out in truck like that, silk socks, and gloves to torture them, likewise a cardboard hat.

Bring back, my son, the armament, we wore in days of yore, them days what's fled and gone, my boy, yes gone to come no more. 'Twas then we had the woollen mitts, the fuzzy knitted kind, the old wool scarf around the neck that hatched fine peace of mind.

And on our head there rested sweet a cap both deep and wide, with fur and wool entwined, by gum, and restin' side by side. And ear-tabs, too, was sprouted there, the things was built to last, and save my brains from being exposed to every wintry blast.

Ah, yes, bring back them things once more, that I may walk about, without a frozen set of feet, without a chilly snout. Yes, let me put those wool socks on, wool mitts upon my paws, a scarf about my chilly neck in either frosts or thaws, and on my dome then place that cap, so I'll raise up my song unto the comforts of the lid what has the ear-flaps on.—ARK.

The Business Paper

AN association of railway executives undoubtedly represents the most capable and progressive business men on the continent. Practically all of them have worked their way up from minor positions and they know every phase of labor, business and public opinion. They should know it better than any other class in the community.

Recently the Association of Railway Executives of the United States wanted to lay before the country the fundamental facts of the railway situation. They selected a number of newspapers for this purpose. Out of the total number, 42 were purely trade and technical newspapers.

In repairing a drawbridge across the Passaic River, at Newark, N.J., it became necessary to remove a casting and pin from a granite pier. After several unsuccessful attempts to draw the pin, as narrated in Stone, the pin projecting down 3 inches into the masonry, it was found necessary to cut a trench in the hard granite so that the casting might be shifted laterally to one side for removal and replacement by a new and larger centre casting. This trench was 4 ft. long, 9 in. wide and 3 in. deep, extending under the old casting. The cutting of the trench would have been an endless task had it not been discovered that an oxy-acetylene flame chipped the granite quite readily and could be used under the old casting without damaging the balance of the masonry. The desired channel was thus quickly obtained. The flame was also used for cutting away the abutment back of the fixed span bottom chord to provide expansion clearance.

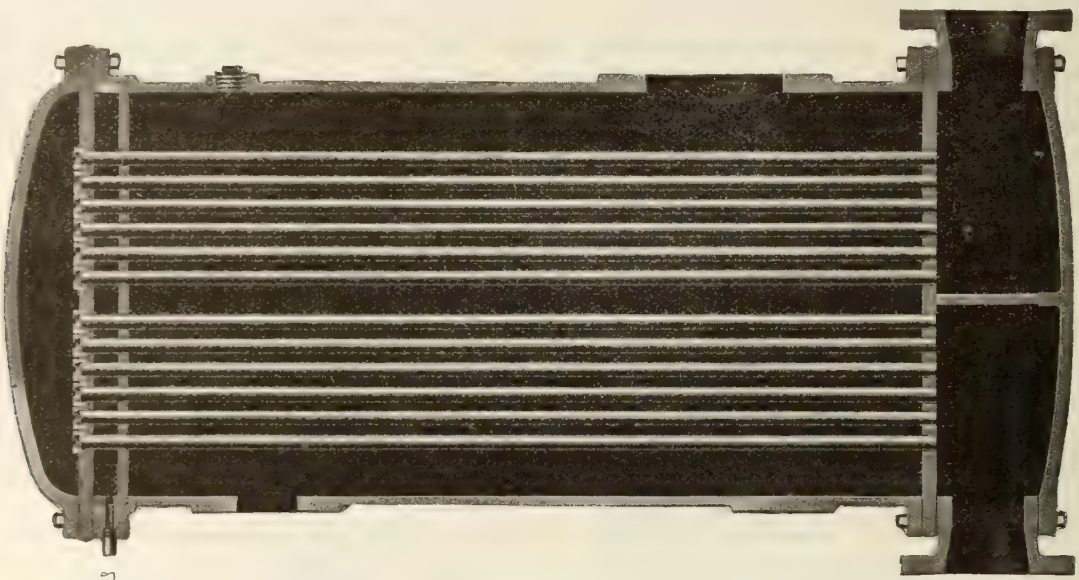
WHILE going through the fitting shop of a large engineering works the manager noticed an apprentice, who was holding his hammer close up to the head, in an unworkmanlike manner. The manager remonstrated with him in this fashion: "Look here, my lad, that's no way to hold a hammer. When I see a man holding his hammer by the end of the shaft I pay him $30 a week. If he holds it half way up I pay him $20 a week, and when its held higher than that I pay him only $10 a week. Do you get me?" "Yes, sir," replied the youngster; "but you might tell me where I should hold it. I only get $5 a week."

The Old Actor—"I'm afraid I'm past playing the hero; but it's something to know that I will have a star part as the villain."
Partridge in "Punch" (London).

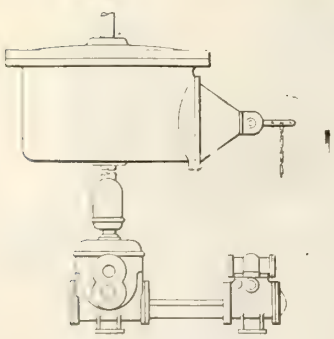
Progress in New Equipment

A NEW WHEELER CONDENSER WHICH ELIMINATES LEAKAGE TROUBLES

It was recently brought up at a meeting of marine engineers that most of the ships now in service are experiencing trouble with leaky condensers. These leaks have been almost invariably traced to the stuffing box between the tube and the tube plate. It has been found that in spite of the kind of packing used, some leakage is practically unavoidable, due to the expansion and contraction of the tube with temperature change.



NEW WHEELER CONDENSER WHICH ELIMINATES LEAKAGE TROUBLES.



The illustration herewith shows a new type of condenser developed by S. Morris Lillie, inventor of the well-known and highly efficient Lillie Evaporator This condenser is used chiefly in connection with salt circulating water on board ship or in regions where the water which is used for circulating purposes would be very bad for boiler feed in case of leakage into the condenser and consequent mingling of the bad water with the condensate.

It will be noted on reference to the illustration, that the tubes are tightly expanded into the right hand tube plate, which eliminates the possibility of leakage at this end. At the other end the tubes are provided with the standard ferrules and condenser packings. It is not considered good engineering practice to expand condenser tubes at both ends, because, due to constant expansion and contraction ,they inevitably loosen, and leakage becomes greater than where packing is used.. The packing permits the tubes to expand freely and yet maintains an almost leakless joint. It is, therefore, at the left hand end that leakage occurs, if at all.

At the left end of this condenser a thin auxiliary tube plate or baffle is provided, through which all of the tubes are passed. The holes in this plate are of such size as to make a sliding fit with the tubes. It is obviously not necessary that these joints be absolutely watertight.

In case of leakage of circulating water through the ferrules and packing, such leakage immediately drops down to the bottom of the compartment between the two tube plates, and is then carried off by the drain shown at the bottom, to which is attached either a small direct-acting condensate pump, or a vacuum trap, depending upon conditions.

We are advised by the manufacturers of this condenser, the Wheeler Condenser & Engineering Co., Carteret, N.J., that they now offer this condenser in all sizes, the cost of which is but slightly greater than the cost of a standard condenser of the same type.

CAUSES OF CLINKER

As clinker is caused by melting of ash any coal will form clinker if the ash is heated to the Melting temperature.

The most common causes of clinker are thick fires, stirring the fire, firing coal containing much slack, closed ash pit doors and fire in the ash pit. Clinker forms in a thick fuel bed because the smaller supply of air through the grate permits the ash to become heated to the melting point. By stirring the fire, ash is lifted into the hotter parts of the fire and fused to clinker. Coal containing much slack may cake or form a crust over the fire, thus stopping the flow of air through the fire in the same way as a fuel bed which is too thick. Closed ash pit doors and fire in the ash pit cause overheating of the grates and the ash above them.

INTRINSIC BRILLIANCY OF THE SUN

The intrinsic brilliancy of the sun, deduced by M. C. Nordmann from temperature measurements made by a heterochromatic stellar pyrometer, shows close agreement with the estimate of Muller, arrived at by entirely different methods.

After allowing for the light absorbed in transmission through the atmosphere, Nordmann finds the intrinsic brightness of the sun to be in the neighborhood of 319,000 cp. per square centimeter, which is about 2,072,000 cp. per square inch. Muller's estimate was 301,500 cp. per square centimeter.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Question.—A certain single non-condensing engine is capable of developing 500 h. p., with 125 lbs. throttle pressure and exhausting at atmospheric pressure. A low pressure turbine inlet is connected to the exhaust pipe of the engine and its outlet to a surface condenser carrying a vacuum of 29 inches. The turbine develops 500 h. p., Explain how you get this power?

Why is it necessary to run turbines at a high rotative speed?

Why is a high vacuum more beneficial to a turbine than an engine?

Answer.—In the engine referred to the steam, at entering, has a temperature of 352.827 degrees F. On exhausting it has a temperature of 212 degrees F. If allowed to exhaust to the atmosphere and condense it will carry with it 1146 BTU's. the total heat above 32 degrees F., per pound on steam.

In putting the exhaust steam from the engine through the turbine, and expanding it to a pressure of 1 pound absolute we have available a further number of heat units from 212 to 102. The amount of heat delivered to the condenser would be only 1133 BTU's. Energy expended by a gas is at the expense of temperature only so we will see how the efficiency of the different points compares.

$$\frac{T - T}{T}$$

$$\frac{460 + 352 - 460 + 212}{460 + 352} = 17.3\%$$

= The efficiency of the engine.

$$\frac{460 + 212 - 460 + 102}{460 + 212} = 16.2\%$$

= The efficiency of turbine.

$$\frac{460 + 352 - 460 + 102}{460 + 352} = 30.7\%$$

= The combined efficiency.

The power to drive the turbine is derived from the heat in the steam which would be lost if allowed to exhaust from the engine to atmosphere. Even then we cannot help losing a considerable amount. The latent at one pound absolute is 1043.015, and there are still 70 degrees sensible heat at that pressure.

Take it this way: You have an engine developing 500 h. p. That is 16,500,000 ft. lbs., per minute. The energy given up per pound of steam is 352—212=140 BTU. Multiply this by 778 to get foot lbs., we have 778 × 140 = 108920 ft. lbs., per lb. steam. This gives a consumption of 18.18 lbs. per hour on the engine, which, of course, is too low practically, but may be allowed to stand for our purpose.

Now the total horse power is 1000, of engine and turbine. That is 33,000,000 ft. lbs. The overall drop in temperature is 352—102 equals 250 BTU's per lb. steam. This is equivalent to 194,500 ft. lbs. Dividing this into the total gives 170 lbs. steam per minute, or 10,200 lbs. per hour divided by 1,000 h.p. equals 10.2 lbs. steam per hour, which is also too low practically. However, the main thing is to point out that the power available is dependent on the drop in temperature.

Turbines must be run at a high rotative speed to get the best results from the steam. In the impulse turbine the potential energy of the steam is changed into kinetic energy by the high velocity and drop in pressure of the steam issuing from the nozzle. The most efficient speed for the turbine vanes is half the velocity of the issuing steam. If this could be attained the steam would drop back from the vanes having lost its motion entirely.

In a reciprocating engine the vacuum in the cylinder is always a pound or two higher than that in the condensor. The free outlet from the turbine enables a higher vacuum to be kept. Another point is that to handle the volume of steam at very high vacuum the proportions of the ports and passages in a cylinder would have to be very large. There is no practical gain in carrying vacuum much beyond 27 inches in a reciprocating engine, but in the turbine well defined gains are made up to the highest vacuum obtainable.

READER'S QUERY RE GRADED CERTIFICATE ACT.

Question?—Could you give me the following information through the columns of POWER HOUSE? Under the new Graded Certificate Act in Ontario, can a man who was a pipe-fitter act as a chief engineer in the same plant, without a license, but having three or more licensed engineers under him? He himself would not stand watch but would have control of plant.

Answer—The interpretation of the Act in this respect is somewhat difficult at the present time, and until it has been in operation for some little time this and other similar questions are not likely to be definitely settled. In general, we would say that the propriety of a man without papers being in charge would depend almost solely upon his jurisdiction, and the scope of his duties. In the first place he cannot operate the plant nor can he take charge of a shift. It would almost seem that he should not give engineering advice, but that his duties should be confined to purely those of an executive nature.

If this were done, and his authority recognized as that of a plant executive, in charge of the engineering end of it insofar as economical operation, etc., are concerned, then we do not see how the act could interfere with him.

It must be remembered that the Act applies only to operating engineers, and it is sometimes difficult to define the latter's duties, and to draw the line between operating and executive duties.

HOW TO HELP THEM.

The following letter from a subscriber, show how POWER HOUSE can help you: Dear Mr. Fenner:

> "Many thinks for your letter re Thermal Efficiency of Reciprocating Engine vs. Turbine. If you have a little time I am enclosing three questions you might send me your answer to. I am greatly interested in Thermo Dynamics, so that you will understand your articles in this last issue comes as a boon and please keep calculus out of it if you possibly can. I got Moyer's Book on Steam Turbines, from the Wiley Series. In your formula of Temperature Mixtures, there is a little error, "Weight of Water" is mentioned twice instead of "Steam and Water." I would also ask "Does not Adiabatic expansion expand at the expense of its own temperature?" Please correct me. I hope you will continue this series with the result that all can see the advantage of the Turbine, and please explain in your series of articles the Entroph diagram relative to the lowest absolute pressure between Turbine and Reciprocating Engines.
>
> Thanking you very much for your past kindness, and in anticipation of future ones, I beg to remain."

The Operators' Point of View

WATER SOFTENERS

A WATER softener should be part of the equipment in every power plant using steam boilers, but from personal observation in power plants I have visited, very few of the plants had them. Many plants have numerous so called labor and money-saving articles of various kinds, some of them are good, some of them only look good, and some of them neither look good or do good. Some otherwise. Good power plant inventions require such constant and careful attention that the proper operation is improperly performed by insufficient care by the perhaps, small operating staff in the plant. A water softener requires attention and intelligent attention at that, but the beneficial results obtained are so great that it would be quite possible to increase the number of helpers in the staff and still be many dollars ahead in operating costs, besides, quite possibly, extending the life of the boiler tubes and shell from 50 to 100 per cent. As a matter of fact experiment has shown that when a water softener is installed the number of the operating staff is usually reduced as the boiler cleaning is reduced to a minimum, repacking and repairing valve rods and valve stems is greatly reduced, pitting and corrosion inside the boiler are much less likely to occur. Numerous men financially interested in boiler compounds will warn the engineer against using caustic soda or soda ash water softeners, the statement has been made that an analysis of most commercial steam boiler compounds will show they contain caustic soda or soda ash. In the plant where I am engineer I use a compound containing caustic soda, the compound is mixed in a thin sheet iron tank, .045 thick, corresponding to number 17-B and S gauge. The compound has been made in this light tank for years, and allowed to remain therein until its contents are gradually used up, remember this is the concentrated mixture, still the iron shows not the slightest sign of pitting or corroding, or thinning. The compound costs $6.00 a barrel and does better work than different compounds I have used costing $75 to $90 a barrel.

The compound consists of caustic soda, japonica, sal-ammoniac, granular, and ground elm bark. Pretty simple surely. It is necessary to have an analysis made of the feed water if the exact quantity of sal-ammoniac to be used is required, but the approximate quantity can be determined with little or no danger of injury to the boiler metal.

About 2 pounds to the barrel will be about right, with 15 pounds of caustic soda and 10 pounds of japonica and 2 pounds of ground elm bark. Feed from one to two quarts of the compound to each 100 B. H. P. per 24 hours.

How to mix the compound:

Place the caustic soda into a barrel. Put several pails of very hot water upon it. Separate the japonica into small pieces and place it in the barrel with the soda solution, stir it up and place the ground elm bark with it, also the sal-ammoniac, granular, and fill the barrel with hot water. When the mixture cools it is ready for use.

Japonica is Japanese flowers compressed into a pulpy mass and nearly odorless. All these drugs can be secured from Lyman Bros, Toronto.

You have the satisfaction of knowing what is in this compound, and it surely will give as good results as most of the compounds mixed and sold to treat waters without an analysis. However the best and safest compound made, fed to the boilers in the best method devised, will not begin to compare with the excellent results secured with a water softener of approved make. Do not miss that word, approved, buy the softener from a manufacturer who is responsible, and do not forget. Keep his guarantee

Any engineer who is interested in this matter should secure one of the books, "Chemistry for the power plant." and learn a few of the simple rules pertaining to water softening; it will prove as interesting as a novel.

A good many of you have employers who would be delighted to install water softeners if you can show them where the profit to them will result, but if he decides to install a machine on your advice let him understand you will not be responsible for results unless he secures a softener of proved worth, let him know that he is not to go around looking for some second-hand discarded junk.

Before bringing the subject to the notice of your employer, secure catalogs from responsible firms, look through the selling section of your power plant journal for the address of such firms.

Do not get the idea that a steam, feed water heater and purifier, and a water softener are practically the same thing, nothing of the kind, every plant over 50 B.H.P. or over should have one of the best of each of these auxilaries as part of its equipment.

James E. Noble.

A SUGGESTION

The Editor:—Being confined to the house for a few days with a badly bruised leg, I have been going through a large pile of back numbers of the POWER HOUSE with a pair of scissors and a paste pot. I found an old well bound diary and have been busy pasting in clippings and have now quite a valuable scrap book.

To read the POWER HOUSE one might imagine that all the steam plants in Canada were burning coal or fuel oil. In British Columbia the manufacture of lumber is our leading industry and a large proportion of our steam plants are fired with wood, sawdust and shavings. Every saw-mill accumulates a far larger quantity of wood refuse than it can consume under its boilers and this has to be burned on the rubbish heap, or in a specially constructed burner. All this heat is absolutely wasted. The saw-mill engineer does not have to study economy of fuel The difficulty he meets with is the varying quality of his fuel which is sometimes so wet that it is very difficult to keep steam at all. Many of the mills are located in remote country districts where skilled help is hard to get and the engineer has to be a very handy man indeed in making repairs to his machinery. I am sure that some of your subscribers among my brother saw-mill engineers could contribute some valuable articles from their experiences if they would.

John Shirley Richardson.

A CORRECTION

A correspondent calls our attention to an error in the article on thermodynamics, namely in finding the resulting temperature of a mixture of water and steam we have neglected to take into account the latent heat. This error occurs on page 33, column 2. Our correspondent points out that the resulting temperature is much higher than 147.4 degrees. the result we gave, and he is quite correct in this. As a matter of fact, the resulting temperature would be 212° unless the mixture was in a closed vessel at a higher than atmospheric pressure. Putting a jet of steam into an open tank of water at atmospheric pressure, will result in a temperature of 212°, no mat-

ter how much steam may be added. Here is one of the fruitful sources of waste in many manufacturing processes, such as dyeing, washing and cleaning tanks such as used in nickel plating works.

To return to our problems, the resultant temperature of 10 lbs. of water at 62° and 5 lbs. steam at 100 lbs. pressure.

The total heat of steam at 100 lbs gauge pressure is 1185. The latent heat is 876.3. We have therefore 5 lbs. steam with a total heat value of 5925 B.T.U. to be added to 10 lbs. water at 62 degrees. Neglecting the specific heat in this case for the sake of avoiding fractions, we get

$$\frac{10 \times 62 + 5 \times 1185}{10 + 5} = 436°$$

Obviously, this is impossible. Therefore we must look back and find how much of the heat is absorbed in raising the temperature, and how much is employed in a different manner.

To raise one pound of water from 62 to 212 takes 150 B.T.U. To raise 10 lbs. requires 1,500 B.T.U. Therefore from the total heat available in the steam, subtract 1,500. 5924—1,500 = 4,425 B.T.U. still available. However this amount of heat will turn a certain amount of water to steam at atmospheric pressure. The latent heat of steam at atmospheric pressure is 966 B.T.U. 4425 ÷ 966 = 4.58 lbs. water turned into steam at atmospheric pressure. Therefore we shall have 10.42 lbs. water at 212° and 4.58 lbs. steam at atmosperic pressure, neglecting the specific heat. which makes only a small difference.

THE TELESCOPIC CANDLESTICK

The telescopic candlestick, designed by J. O. McDonell, and shown on page 97. The POWER HOUSE is not likely to be used by many engineers. Electric light is used in nearly every power plant at the present and an insulated waterproof socket and extension wire is away ahead of anything like the outfit suggested by Mr. McDonnell. Five pieces of round wood, about ¾ inch in diameter, and 5 feet long with thimbles at each end so that they can be put together like a fishing rod would be a lot simpler and handier than the pulley extension rig shown. For seeing the inside of a boiler through the end handholes where there is no electric light, a nail driven through one end of a long stick and a piece of candle forced onto the nail, is a hard thing to beat. To use a candle in restricted places use the pantograph. As this instrument is about a thousand years old and is used considerable in engineering practice, most engineers know all about it.

A handy size to make is from strips of hard wood 19 inches long, ½ inch wide, and ¼ inch thick. Make holes for ⅛ inch bolts ½ inch from each and tighten the nuts on the bolts pretty tight.

The size of this pantograph when folded will be 19 inches long, 3 inches wide and ½ (half) inch thick. Therefore it can be kept in a desk, cupboard, box or even a suitcase.

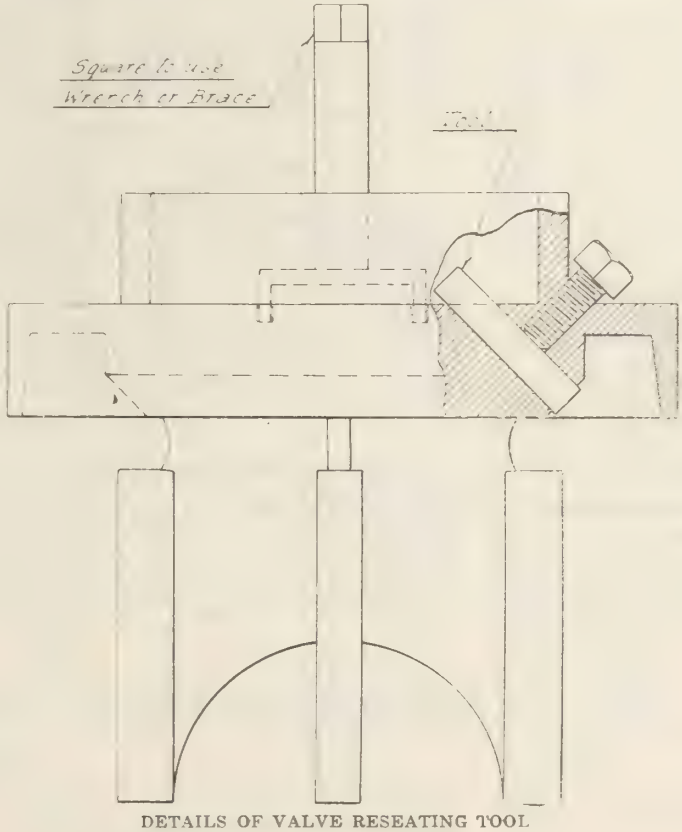
It will extend from 19 inches up to 9 feet and can be used in any position, flat, upright or at any angle. Use a thin candle or a short piece of candle on the end. It is a good idea not to use candles inside steam boilers if there is any possibility of having a properly protected electric light outfit. Many engineers in small country plants use the dry electric cell lantern when cleaning the boilers.

Cases have occurred where cleaners have left candles inside the boilers, these candles would melt and prove a source of danger as a burned boiler shell would be possible.

W. Whip.

VALVE RESEATING TOOL

I had occasion to repair some very much worn safety valves, and as the discs were too badly damaged to be worth machining, some new ones were ordered. I took one of the old ones, drilled it through the face as shown in the sketch, and put in a cutting tool, using a set screw to hold the tool in proper adjustment. A forked tool with a square shank was used to attach the brace or handle to turn disc, there being two holes in the top of the disc formerly used for grinding in purposes. The seats were deeply grooved but this arrangement served very well to smooth them down and made the work of grinding in very easy. It has the advantage of being easily and cheaply made and the material needed is usually to be found about any power plant. The guide vanes help to keep disc central and if tool is not set too deep there will be very little chattering.



DETAILS OF VALVE RESEATING TOOL

Allen Norgrove.

CARRY A THIN, LEVEL FIRE OVER THE ENTIRE GRATE

A fuel bed of uniform thickness should be carried over the entire grate, so that combustion takes place at the same rate in all parts of the furnace. If the bed is not of uniform thickness too much air may flow through the thinner spots, while too little may flow through the thicker parts due to their greater resistance.

The thickness of the fuel should vary according to the draft, but in all cases should be thin enough to allow sufficient air for complete combustion to flow through it. Just how thick a fuel bed should be cannot be said offhand, as the thickness which should be maintained in any particuar plant depends upon the kind and size of fuel and the draft. With coals commonly used in Iowa, fuel beds should be from 4 to 6 inches thick to give the best results in most plants. Fuel beds less than 4 inches thick have a tendency to allow air to pass through without giving up its oxygen on account of the small holes that are usually found in them.

Announcement

The Canadian Farnsworth Company, Engineers and Manufacturers of Condensation Pumps, Automatic Boiler Feeders, Return Steam Traps, all of the Duplex Type, and General Steam Utilities, have opened and are now operating their new factory, at 1-24 Hillingdon Avenue, Toronto. These lines formerly manufactured by the Canadian Fairbanks-Morse Company.

This new organization is under the management of Mr. W. H. Rose, who was well known to engineers as General Manager and Chief Engineer of the Geo. W. Cole, Limited, Toronto.

The Farnsworth line is thoroughly well known, having a world-wide reputation for efficiency in manufacture.

The largest order for Condensation Appliances ever placed is now in process of manufacture by this Canadian Company, for use in a Canadian plant, and consists of a number of Automatic Boiler Feeders of 1000 h.p. each, and a quantity of Lifting, Separating, Condensing Types of Machines. Photos of this installation will appear in later issues of Power House.

NEW LINES FOR THE INGERSOLL-RAND CO.

Deals Completed for Making and Selling Several Lines in this Country

Arrangements have recently been concluded between the Wellman-Seaver-Morgan Company, of Cleveland and Akron, Ohio, and the Canadian Ingersoll-Rand Company, Limited, whereby the latter firm are now making and selling in Canada the Wellman-Seaver-Morgan line of Rubber Mill Machinery. The latter comprises crackers, washers, mixing and warming mills, grooved rolls, refiners, calenders, reduction gears, fabric dryers, vulcanizing presses, tire rimming and applying presses, tubing machines, accumulators, high-pressure pump, etc. The Canadian Ingersoll-Rand Company, Limited, will also take up the manufacture in Canada of Wellman-Seaver-Morgan hydraulic turbines, and a department for this work is now being organized.

The Canadian Ingersoll-Rand Company have also been appointed Canadian agents for, and manufacturers of, the Ryther and Pringle line of wood preparing machinery, for use in ground wood and chemical fibre mills, consisting of slashers, swing saws, kickers, loaders, log hauls, splitters, chip screens, shredders, etc., including the Barienger Braking Device for lowering heavily loaded sleighs or other vehicles down steep slopes, and will also manufacture and sell the Bird Machine Company's pulp and paper mill specialties, comprising Bird Inward Flow, Rotary Screens, Walpole Screens, Beating Attachments and Save Alls.

TRADE GOSSIP

To Erect School.—The York County Building Department issued building permits for work aggregating $30,000. A portable school house will be erected on Danforth Heights at a cost of $3,500.

Clay Workers' Association Meets.—At the annual convention of the Clay Workers' Association of Western Ontario held at London, Ont., the president, Mr. C. S. Parker, urged the members to keep up with the times in the use of machinery, thus reducing costs and raising production. Addresses were also delivered by members of the committee.

Belgian Orders for Canada. — Large orders for Belgian locomotives are expected to be secured by Canadian firms in the near future. Senator Nicholls, of the Canadian General Electric Co., stated that he had received a long cable communication on this subject, but declined to say any more at the present stage of the negotiations.

Big Increase in Customs.—The eleven months of the fiscal year show a big increase in the Customs receipts. A statement issued by the Department gives the following figures: $163,527,100, as against $143,564,204 for the corresponding period last year. For the month of February alone the increase was $3,481,688.

Plans Big Improvement.—Extensive improvement tending towards increasing the capacity of the Consolidated Mining and Smelting Company, Trail, B.C., is making rapid strides. The plans call for improvements in the copper refinery estimated at $250,000, the erection of a rod mill to cost $200,000 and the erection of a large addition to the machine shop.

To Build a Dam.—The municipality of South Vancouver are making application to the Provincial Comptroller of Water Records for authority to construct a storage dam at the outlet of Loch Lomond. The proposed reservoir will have a capacity of 3,000 acre feet and will flood about 20 acres of land. The reservoir will be used to supply South Vancouver with water.

The Annual Refrigeration Number of Power House

will be issued on April 20th. This issue presents a splendid opportunity for advertisers of ice and refrigeration equipment to bring their name and lines favorably before the Canadian trade.

Arrange Now for Special Advertising in the REFRIGERATION NUMBER

Fuel Board Continues.—The President of the United States has, by a special order, continued the existence of the Fuel Administration, its powers being lodged in a committee of four. The Railroad Administration, which is being discontinued from March 1, has been exercising the functions of the Fuel Board, but the situation is considered so serious as to warrant the continuance of the Fuel Board.

To Manufacture Oxygen.—A $5,000,000 corporation has been formed by Montreal and Toronto capitalists for the manufacture of 100 per cent. pure oxygen. Plants are being established all over Canada. The Toronto branch, known as the National Electro Products, Ltd., has been making oxygen for some time at the plant at 297 Dufferin Street. The Toronto directorate includes W. J. Cluff, president; W. W. Nearn, R. J. Cluff and A. J. McDougall. The Montreal group are represented by H. W. Beauclerc, G. H. Duggan and W. F. Angus.

NEW CATALOGUE

The Beaudry & Company, Inc., have issued a very attractive catalogue on their line of power hammers. Both belt and motor driven types are shown; together with the various features peculiar to this line of tools. To anyone interested in power hammers this catalogue should especially appeal.

CATALOGUES

The Sterling Engine Company of Buffalo, N. Y., have issued a bulletin, descriptive of the Model G. R. Sterling Marine Motor. While this folder describes engines up to 300 h.p., it is intended to construct the series up to 450 h. p.

These engines have been developed from previous models, and are not a radical departure from Sterling practice. To an engine that has proven itself in the past six years as being one of the best the market affords, the makers have added a detachable cylinder head, containing overhead dual inlet and dual exhaust valves, in addition to which various bearing surfaces have been increased, and by exhaustive testing the correctness of the design of the overhead valve operating mechanically has been proven.

The Sanford Riley Stoker Company, Worcester, Mass., have issued a new publication on "Riley Underfeed Stokers." This stoker takes up the various details of the stokers manufactured, and is particularly interesting to the engineer on account of the engineering data relative to installations contained in it.

The Garlock Packing Company, Hamilton, Ont., have issued an attractive calendar of considerable usefulness to power plant engineers.

The Builders' Iron Foundry have recently published a new four-page, two-color bulletin, No. 197, entitled "Why your power plant needs a venture."

PORTABLE BELT CONVEYORS.

Portable belt conveyors for handling material horizontally or at a slight incline are described and illustrated in a new folder, entitled "Type B Portable Belt Conveyors." This folder, just published by the Portable Machinery Co., of Passaic, N. J., contains prices of these machines which are made with 16" wide belt, and in standard stock sizes, as follows: 12'-6", 16', 19'-6", 23', 26'-6", 30', 35'-6" and 37'.

These machines in addition to being used for handling coal, sand, crushed stone, fertilizer, etc., are being used for conveying many manufactured products, bagged material, such as cement, etc.

Used in series or in conjunction with fixed conveying system, they afford a flexible, convenient and automatic conveying arrangement.

The Green Fuel Economizer Co., Beacon, N. Y., and the Kent Building, Toronto, have issued a publication on "Green's Hi-Efficiency Radial Flow Fans" for forced draft. This bulletin No. 152, in addition to a description of the fans and their applications, contains dimension tables and other engineering information relating to their use.

SAVING FUEL AUTOMATICALLY AND SCIENTIFICALLY IN THE BOILER ROOM.

This is the title of a new 24-page booklet published by the Northern Equipment Co., Erie, Pa. It is based upon matter that was prepared for the United States Fuel Administration during the war. In the preface of the booklet the manufacturers say: "When the war ended we thought we had done our duty, and that the fuel situation would ease up a bit. However, we find the fuel problem now becoming serious. Prices will not come down because wages will evidently stay up or will go higher."

The booklet compares hand and mechanical feeding with mechanical regulation, as performed by the Copes Regulator. It shows in a convincing way what is to be desired in the way of scientific boiler feed regulation.

Use The LONG STEAM for TRAP SATISFACTION

Automatically drains jacket kettles, separators, steam mains. Works against 1 to 20 pounds pressure. Has two outlets and is installed in any position. DOESN'T FREEZE.

The Hamilton Powder Works, Beloeil, P.Q., use them with success. Read this letter.

Dear Sir: We have used one of your steam traps for a long time and have found the same to answer the purpose as well as any seen in operation. We were so pleased with the working of this steam trap last winter that we ordered six more this season and have fitted them up at various points in the works where live steam is used for heating purposes.

(Signed) J. Murray Wilson, Superintendent

Our trap will give you the same satisfaction as recorded above. Investigate and you'll be satisfied, too.

NON-CORROSIVE CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

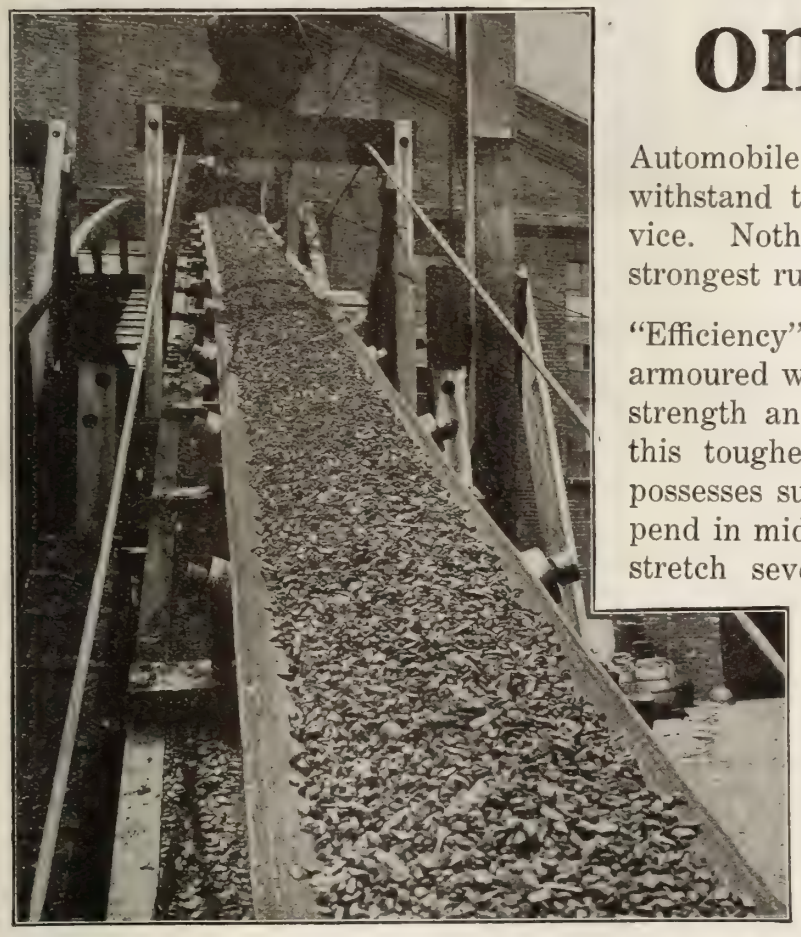
Conveyor Belts that Stay on the Job



Automobile Tire Treads encounter and must withstand the most abusive, abrasive service. Nothing but the very toughest and strongest rubber stock will stand it long.

"Efficiency" Conveyor Belts are heavily armoured with Tire Tread Rubber of great strength and elasticity. A single cord of this toughened rubber, one inch square, possesses sufficient strength to readily suspend in mid air a big load of hay and will stretch several times its original length without breaking.

"Efficiency" Conveyors, like highest grade Auto Tires, are made for the most exacting service.

Though of immense strength they trough perfectly, and, of their own weight, automatically conform to the idlers.

Other very important features in their construction we are unable to detail here, but they represent economy in operating cost for you. When in need of Conveyor Belting let us send a representative to demonstrate them.

UND. LAB. INSPECTED

ECONOMY Renewable FUSES Mean DOUBLE PROTECTION

ECONOMY renewable FUSES were approved—IN ALL CAPACITIES—by the Underwriters' Laboratories on Dec. 9, 1919—the old "APPROVED IN ALL CAPACITIES" renewable fuse using an inexpensive bare link to restore a blown fuse to its original efficiency.

Economy renewable Fuses—from 0 to 600 Amperes in both 250 and 600 Volts bear the Underwriters' approval label. Economy "Drop Out" renewable links also bear the inspection symbol.

There were millions of Economy Fuses in use before this approval was granted—a fact applicable to no other electrical device listed in the code as requiring approval.

Both the unrestricted use of Economy Fuses and the granting of approval were due to the fact that these fuses live up to all claims made for them — accurate, efficient, economical and safe.

The use of ECONOMY renewable FUSES means double protection—the dependability of the fuse itself—the regular inspection by the Underwriters' Laboratories.

Approved In All Capacities

Economy Fuses, approved in all capacities, ferrule and knife blade types, are stocked and sold by all leading electrical dealers and jobbers in the United States and Canada.

"The Jeffrey Carrier Will Cut Down Our Operating Expenses"

THERE'S but one way that we can fight increased costs and that is to use mechanical equipment wherever possible. In the boiler room a JEFFREY Carrier will handle our coal and ashes for a fraction of our present costs. "The Carrier will also relieve the men of the disagreeable job of handling hot, dusty ashes in wheelbarrows.

"I have studied the JEFFREY blue prints and specifications very carefully and must admit that they are actually putting out the 'last word' in coal and ash handling machinery."

Our new Catalog No. 210-4 tells all about the JEFFREY Improved Carrier. Write today for your copy.

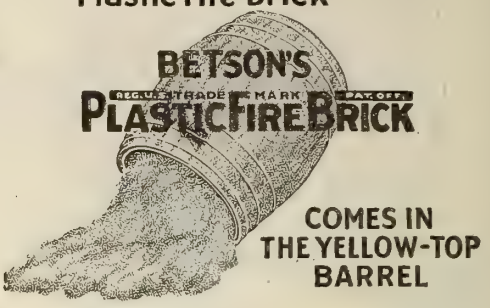
Handle it Mechanically

There Is Only One Plastic Fire Brick



Anyone

can see that the weakest parts of a boiler lining are the joints.

The logical remedy is to have no joints—to cover all the brick work with a one-piece, monolithic furnace lining.

But the ordinary fire brick is not elastic. If you used it for this work it would crack and crumble away to dust.

The successful furnace lining is

BETSON'S

REG. U.S. TRADE MARK PAT. OFF

PLASTIC FIRE BRICK

It is the pioneer and a tried boiler refractory material. It has twenty years' practical experience behind it. It is elastic—won't crack and crumble.

There is nothing about a Betson lining to loosen or fall down. Use it in the furnace, on door arches, on rear arches, on baffles, bridge walls, etc.

Practical booklet on furnace linings sent free.

The Truth About Vulcabeston Packing

Sometimes the full truth is as dangerous as exaggeration — it taxes credulity too far.

But here are some facts about Vulcabeston Red Fibre Sheet Packing that are easily proved. Vulcabeston gaskets stood (and are still standing):

300 lbs. steam pressure with 200° F. superheat
1350 lbs. carbonic gas pressure
350 lbs. compressed ammonia
1500 lbs. hydraulic pressure
1300 lbs. compressed air

Vulcabeston has never failed under normal working conditions or unusual and abnormal tests.

You can depend upon Vulcabeston gaskets with perfect confidence. It is "The Universal Packing."

The Johns-Pratt Company
Hartford, Conn. U. S. A.

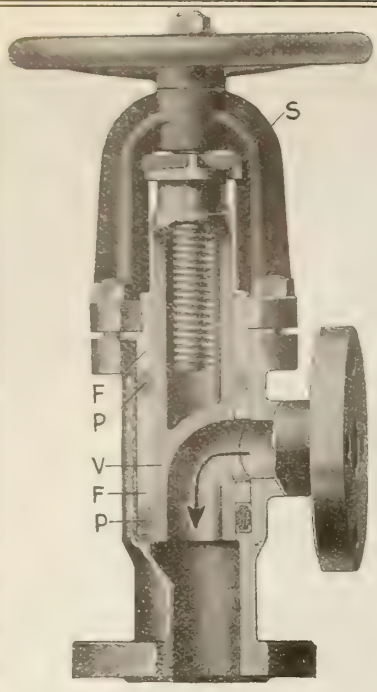
"VULCABESTON" RED FIBRE STEAM SHEET PACKING COMPRESSED ASBESTOS

20-3

VULCABESTON



OPERATION

In closing valve, shoulder "S" on plunger "V" engages the loose follower gland "F" compressing packing "P" above and below the port, making an absolutely tight valve.

YARWAY
Seatless Blow Off Valve
formerly the
SIMPLEX

Has eight important features

1. It is seatless.
2. It is simple. There is but one moving part besides the wheel and spindle.
3. Friction is reduced to a minimum.
4. Packing is protected from the blow-down and rarely needs replacing in less than two or more years, generally much more.
5. When closed, the packing is automatically compressed, making the valve absolutely tight. And the packing will not work loose.
6. Packing remains stationary in body and does not have to pass the port or opening, a feature afforded by no other valve.
7. The port opens slowly, thus avoiding danger to workmen and boiler tubes from shock of sudden opening.
8. Passageway is clear and unobstructed. There are no pockets to gather sediment.

You can try a YARWAY Seatless Blow-Off Valve on one of your boilers for 60 days. You are not required to keep it unless this trial convinces you that you cannot afford to be without it. Write to-day, stating size of blow-off line and whether you want angle or straightway, flanged or screwed.

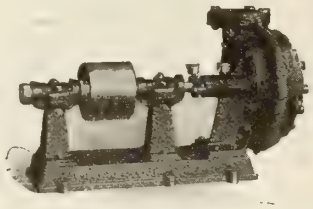
AMERICAN-MARSH PUMPS

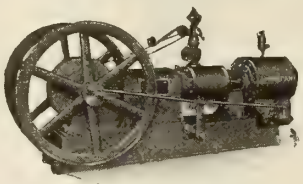
SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

New Truths and Old Fallacies
Announcement

For some time hereafter we shall devote our advertising space to discussing white metal alloys used for lining bearings — generically termed Babbitt Metals.

We are conscious of the limitation of our knowledge in this connection, but shall, nevertheless, attempt to clarify this somewhat hazy subject for the benefit of those who have had less opportunity to study it.

We make no pretense of undertaking this from altruistic motives, as, of necessity, many of the figures and facts that will be presented come from tests of Magnolia Metal in comparison with other Babbitt metals, both in laboratory tests and in actual service, showing conclusively the superiority of Magnolia Metal; and we shall also point out the reasons for this superiority.

At first glance some of our ideas may appear radical in their departure from long established customs, but they are supported by a strong array of figures and facts which, we think, will leave but little room for dispute and we shall try to make the presentation in a logical, unbiased way, as free of technicalities as possible.

We invite criticism, corrections and contribution of ideas, as by collaboration we may thus evolve a practical working basis; or, at least, form the ground-work upon which others, better qualified, can build.

A great deal of important work has been done already in connection with white metal alloys, but in a detached way, not usually in relation to babbitt metals, because that was outside of the scope and experience of most investigators.

Continued next month.

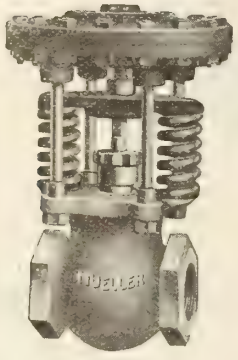
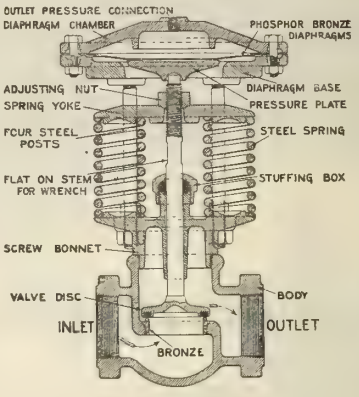
MUELLER

Reducing and Regulating Valve and Pump Governor

For Steam and Oil; Single Seat; Direct Operated



No. A5120
Code—*Ranchero*



This valve is for protection against abnormal rises in initial pressure and where a reasonable variation in the delivery pressure is not objectionable.

For pump governors, power purposes and blower engines it is unexcelled.

It operates most efficiently where the initial pressure is constant and the required reduction is not too great.

Regulators of this description are suitable for pressures up to 150 pounds. For pressures in excess of 150 pounds, submit specifications.

WE MAKE MUELLER

Basin and Bath Trimmings, Bibbs, Sill Cocks, Ferrules, Curb or Service Cocks, Corporation Cocks, Tapping Machines for Water and Gas, Service Clamps; Regulators and Reducing Valves for Water, Air, Steam and Oil; Bubbling Fountains, Gas Cocks, Globe, Angle and Check Valves, Etc. Forgings in Brass; Castings in Brass, Bronze and Aluminum; Specialties for Automobile Companies, including Bronze Bushings, Gasoline Cocks, Etc.

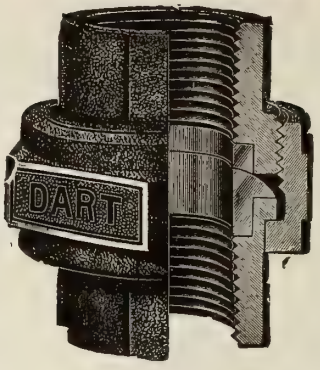
Mr. Buyer---



Do not condemn all ground joint unions because you have had trouble with some said to be "just as good" as the "Dart"

You know what the imitations did. Now put a genuine "Dart" on that joint and it will prove to you that there is a vast difference in unions and also prove, that there is a decided advantage in using "Dart"

These unions are guaranteed to give satisfaction any failing will be replaced two for one or your cost, money refunded.

Judge for yourself, you take no risk - Know what using Dart Unions will mean to you.

Jobbers throughout Canada sell them.

The trap that keeps the radiator hot

Any kind of a boiler will shove the steam up to a radiator. But it takes a mighty good trap to let all the air and water out without letting steam into the return line.

The Dunham Trap has been doing it since 1903—and doing it so well that you don't see many old-style traps nowadays. Everybody is busy pushing thermostatic disc traps. But do not forget that the Dunham was the FIRST radiator trap of this type.

The **first** of its kind—and the **best** of its kind according to many, many engineers, and to architects and heating contractors who know that quality counts above all else.

Our new booklet, "Data on Dunham Heating" telis some heating facts in an interesting way. May we send you a copy?

The Quality Standard That Produces "Plus Service" Belting

The only sure way to get satisfactory service is to buy products of known worth.

In Dominion Rubber System Belting, the worth is known because every ounce of material—each individual operation and each finished belt must test up to the highest quality standard ever made for belting.

From the time the materials come into our factory until the belt is running on your pulleys, there is no chance of your getting any thing but "plus service" belting.

This is the result of over fifty years of belt making experience and research by the oldest, largest and most completely equipped rubber organization in Canada.

The rubber that goes into Dominion Friction Surfacing Belting is not a mere waterproofing substance—our chemists have given it a far greater value by making it into a friction compound that prevents practically all power wastage on the pulleys.

"Plus service" includes the free technical advice of our belting engineers who are ready to help you with your transmission and conveying problems without placing you under obligation to us.

A phone call, wire or letter to our nearest branch places all of our facilities at your disposal.

JEFFERSON

Underground

Take a trip underground—listen to the music of the pumps—"CHUG, CHUG, CHUG" — twenty - four hours a day, and you'll realize the importance of dependable unions. The failure of a single union might cause serious consequences involving loss of life and heavy damages.

JEFFERSON UNIONS will render perfect service as long as the pipe line holds out. Once you put a JEFFERSON on the line, you can say "Good-bye" forever to pipe line troubles.

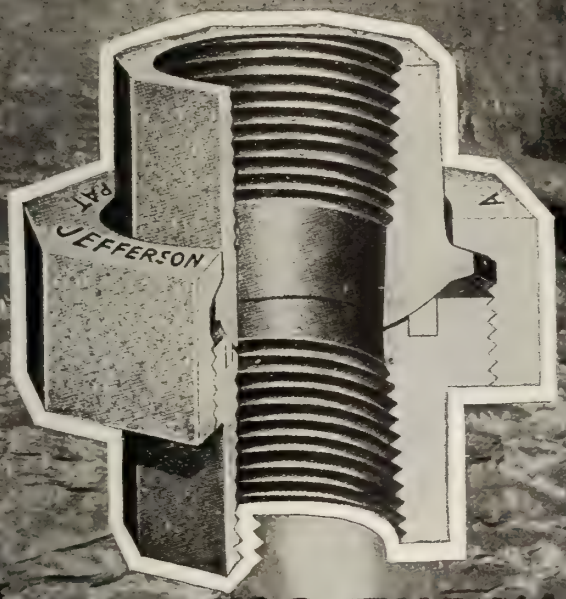
Insist on genuine JEFFERSON Unions – the name on the nut protects you from the "Just-as-good" variety.

Talk over unions with your jobber. He has JEFFERSONS in stock and can tell you why JEFFERSONS always make good.

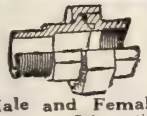
Write for our catalog "UNIONS"

Jefferson Union Co.

Lexington, Mass.

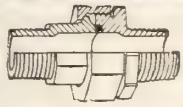


"LOOK FOR THE NAME ON THE NUT"



Male and Female Union Takes the place of an all-female union and a nipple. Makes a short connection.

Union Elbow, all female. Takes the place of a straight union, nipple and an elbow. Also made male and female.



All Male Union. Saves two pipe joints between two female threaded parts.

Why you get

better service from LUNKENHEIMER "VICTOR" GATE VALVES

THE disc is a solid wedge, seating on rings which are threaded into the body in exact alignment with the disc faces; the disc is guided by ribs cast in the body, and travels to practically a closed position before coming in contact with the seatring faces. "Dragging" of the disc across the seatring faces is thereby eliminated, preventing the wear so prevalent in valves employing loose parts.

When wide open the top of the disc seats directly beneath the stuffing box, relieves the packing from pressure and permits repacking while pressure is on.

The gasket between the body and bonnet flanges is an exclusive Lunkenheimer feature. It consists of a seamless copper wire partly embedded in a groove in the body flange; will not blow out and is practically indestructible.

Bearings are bronze bushed and all parts, including the seatrings, are renewable.

Inside Screw Stationary Stem and Outside Screw and Yoke Rising Stem types for working steam pressures up to 350 pounds.

Installing Lunkenheimer "Victor" Gate Valves means permanence and satisfactory service.

Can Any Evidence Be More Convincing than Repeat Orders?

Repeat orders are the highest expression of confidence. It is significant that to-day, eighteen years after their manufacture began, over 60 per cent. of all Diamond Soot Blower business consists of re-orders from former purchasers.

Every American industry of any prominence contains many representative members who almost invariably purchase Diamond equipment whenever they put in additional mechanical soot blowers. To mention a few prominent purchasers:

	Number of Orders	Number of Boilers Equipped
General Electric Company	26	60
Ford Motor Company	11	26
Solvay Process Company	15	53
Brooklyn Edison Company	16	56
Armour & Company	16	53
General Motors Company	12	34
Du Pont Powder Company	22	115

These seven concerns within a period of a few years placed 118 orders to equip a total of 397 boilers. There is nothing casual or accidental in this record. The market superiority in design and construction of Diamond equipment —the high and uniform quality of the service rendered—and the notable savings effected in fuel and labor are the underlying causes of these large purchases just as they are the foundation of the largest soot blower business in the world.

If your boilers are not equipped with Diamonds, ask for Bulletin 280.

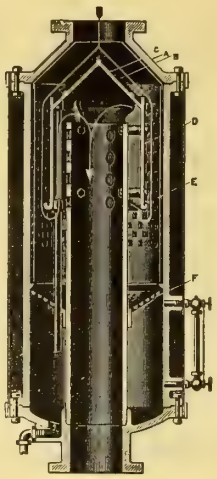
III IMPORTANT THINGS
TO CONSIDER ABOUT A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

METLSKIN

prevents boiler-scale

by a process which is mechanical, rather than chemical. It forms a minute, grayish-white coating which keeps scale-forming solids from adhering to the boiler metal, and, therefore, these solids must settle to the mud-drum, whence they may be discharged through the blow-off.

METLSKIN is distinctly **not a compound,** nor does it contain any soda ash, graphite, kerosene, or tannin. It works by expansion, without harm to anything save boiler-scale itself.

The Two Months' Test

may be adopted by any reputable concern troubled with scale. METLSKIN will remove the old incrustation safely, but gradually, will ultimately produce clean boilers and then **keep them clean.**

Send a post card for terms and full details.

NOPORO

air-proofs boiler-settings

by maintaining an air-tight seal on the exterior surfaces of the brickwork. After a thorough application, by means of a trowel, NOPORO forms a covering that looks and feels very much like coarse, black grain leather. The surface may be whitewashed after an interval of 6 to 8 days, while the material below the surface retains its plasticity. It will not peel, check, or disintegrate, and will **stay put** for years. No further attention need be given it.

An Immediate Saving

may be effected, since NOPORO promptly prevents the entrance of cold-air into the furnace chamber. That means better fuel-combustion, less firing, less coal. NOPORO pays for itself from the first.

Mail a card for prices and descriptive folder.

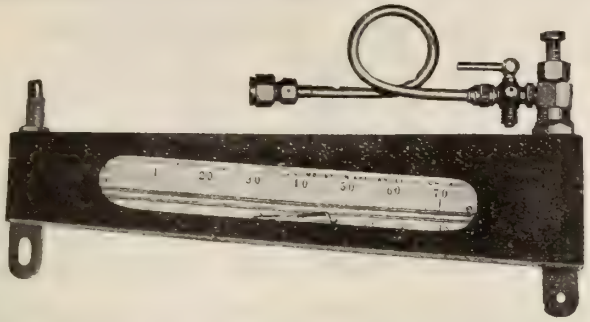
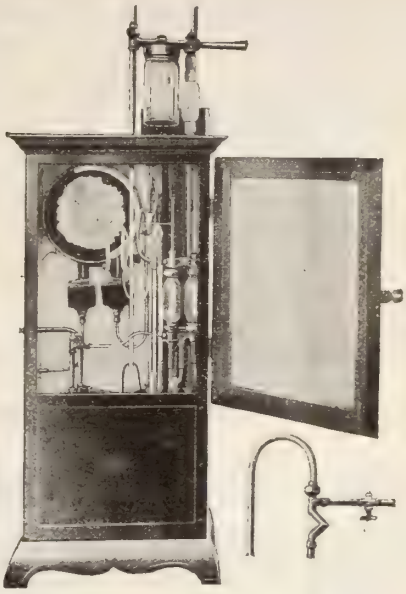
SECRETARY OF THE WAR PURCHASING COMMISSION, BOOTH BUILDING, OTTAWA

February, 1920



The Hays Draft Gage

The Hays Differential Draft Gage indicates the draft over the fire, the draft in the last pass, or the drop in draft between the last pass and the furnace. There is practically no maintenance expense connected with its operation. Tubes will not break.



The Hays Automatic CO_2 and Draft Recorder

The exact reason why 30 to 50 per cent. excessive amount of fuel is consumed in your plant is shown by the Hays CO2 and Draft Recorder. With these appliances installed, your firemen can fire intelligently; they will work with accurate facts before them instead of groping in the dark.

FUEL is Scarce and High in Price

You Can't Afford to Waste It

Excess or insufficient air, leaky boiler setting, leaky baffles, holes in the fire, fire too thin or too thick, draft too weak or too strong—these are some of the faults which waste your fuel and they all can be prevented by adopting

HAYS COMBUSTION EFFICIENCY APPLIANCES

You can't locate losses by guess work. Hays appliances lift furnace attention from guess work to exact knowledge. They indicate exactly where fuel is being wasted. Then your engineer is in position to stop it.

Hays Improved Gas Atomizer

For testing boiler furnace gases, producer gases, casing-head gas, exhaust from internal combustion engines, gases from sulphur burners, nitric acid gases, chlorine gas, etc., etc.

For the Small Plant as Well as the Big Plant

Small plants are very apt to consider that Hays Apparatus is only for big plants. This is not the case. Small plants can reap the greatest of benefit from Hays equipment. They can secure 100% efficiency.

HAYS SERVICE—Just what Hays Combustion Efficiency Appliances can accomplish in your plant may be put up to our Service Department. Their service costs you nothing.

Let us send you complete literature describing and explaining Hays Apparatus. It will prove to you that you need Boiler Efficiency Appliances—by giving you countless sound reasons for equipping immediately with Hays Apparatus.

WATSON & McDANIEL CO.
No. 146 N. 7th Street, PHILADELPHIA, Pa.

The Simplest and Best Cleaner on the market is

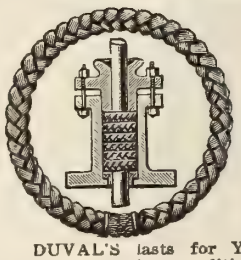
PILLEY'S

Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over. A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.

For sale by leading Canadian jobbers.

Manufactured by

PILLEY PACKING AND FLUE BRUSH MFG. CO.
623 South Third Street - - - St. Louis, Mo.
Eastern Office: 71 Fulton St., New York.



DUVAL'S METALLIC PACKING

for

ALL CLASSES OF ENGINES

and the

Highest Superheated Steam

DUVAL'S lasts for YEARS without renewal and keeps the rods in perfect condition. It is placed in the glands the same way as ordinary soft packings. Over 600,000 glands packed.

"BENHYCO" JOINTING FOR STEAM AND HYDRAULIC JOINTS. Supplied 48" square, 1/32" thick and up. Stock carried in Montreal.

DEPARTMENT OF LABOUR

Ontario Government

Minister:
Hon. W. R. Rollo.

Deputy Minister:
W. A. Riddell, Ph.D.

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a STATIONARY steam plant of 60 B.H.P. or over, in the Province of Ontario, must hold a Stationary Engineer's certificate from the Board of Stationary & Hoisting Engineers. Anyone operating such a plant without a certificate is liable to the penalties set forth in the Act respecting Stationary and Hoisting Engineers.

After January 1st, 1920, the Certificate issued by the Board will be of four grades, viz., First, Second, Third, and Fourth. Application forms for graded certificates will be mailed upon request after the above-mentioned date. The certificates now issued by the Board will be graded into Third and Second-Class upon renewal, same being classified from the information contained in the renewal application which will be sent to each certificate holder.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse-power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a certificate is liable to the penalties set forth in the Act respecting Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1st, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request. The B.H.P. and other information contained in these forms is to be used for statistical purposes. A Registration Certificate will be issued to each applicant. All applications, or requests for same, should be mailed to the Chairman.

W. C. MCGHIE, CHAIRMAN OF BOARD

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., c. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

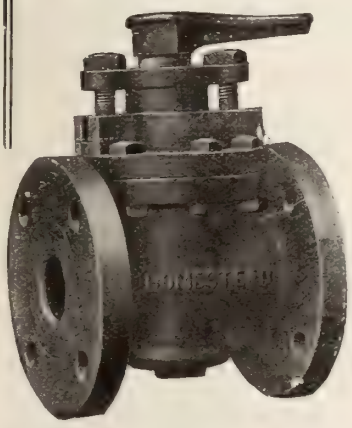
All communications should be addressed to the Steam Boiler Branch, Department of Labour Parliament Buildings, Toronto.

D. M. MEDCALF, CHIEF INSPECTOR OF STEAM BOILERS

No Time Lost When You Use HOMESTEAD QUARTER-TURN VALVES

Adopt Them!

Many a break-down and shut down may be avoided by using Homestead Valves. They are rendering more than satisfactory results to thousands of satisfied customers, who back up their experience by ordering more "Homesteads" whenever they are in need of tight, efficient and positive acting valves.



You should adopt "Homesteads" for all classes of severe service. They are all constructed with the Patent Homestead Process which makes them seatless while the pressure is passing through and which permits their being operated easily and safely.

Order your requirements to-day.

Insure Constant Level

The most economic way to operate boilers is with constant water level and uniform constant inflow. With the level held constant at middle gage, the greatest amount of heating surface is presented to the hot gases and the maximum amount of steam space is available.

Vigilant Feed Water Regulators

meet these conditions in a very satisfactory way.
They are easily adjusted to maintain an absolutely constant water level at any arbitrarily determined height in boilers, and they feed continuously with perfect uniformity.

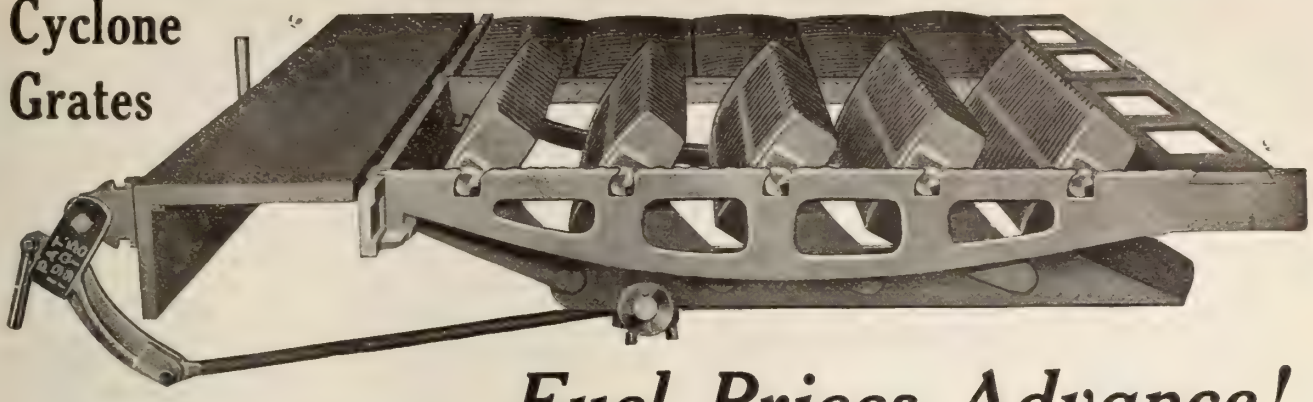
Cyclone Grates



Fuel Prices Advance!

Put in On Trial Basis

You take no chances in putting Cyclone Grates to the test. We are prepared to install them on a trial basis for 30 days. Write for our proposition and let us explain the principle of the grates in detail. Our trial offer is genuine; take immediate advantage of it; every day you miss having Cyclone Grates in your furnaces means lost money.

You have seen this heading in the newspapers from time to time, and you will see it again. You need the coal and you will have to pay the high prices — but you won't feel the effect if you install CYCLONE SHAKING AND DUMPING GRATES.

CYCLONE GRATES give you more heat units with less coal. They burn hard coal or soft coal of the cheapest grades and give maximum results. They get the most heat out of screenings. Cyclone Grates give 60% air space and 90% underdraft. No clinkers, no waste.

Enquiries Gladly answered.

Buyers and Sellers of New and Used Machinery

A CONTINENT-WIDE SERVICE

When Buying Thermometers
There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.
Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

Get a copy of Catalog P.H. 200 to-day.

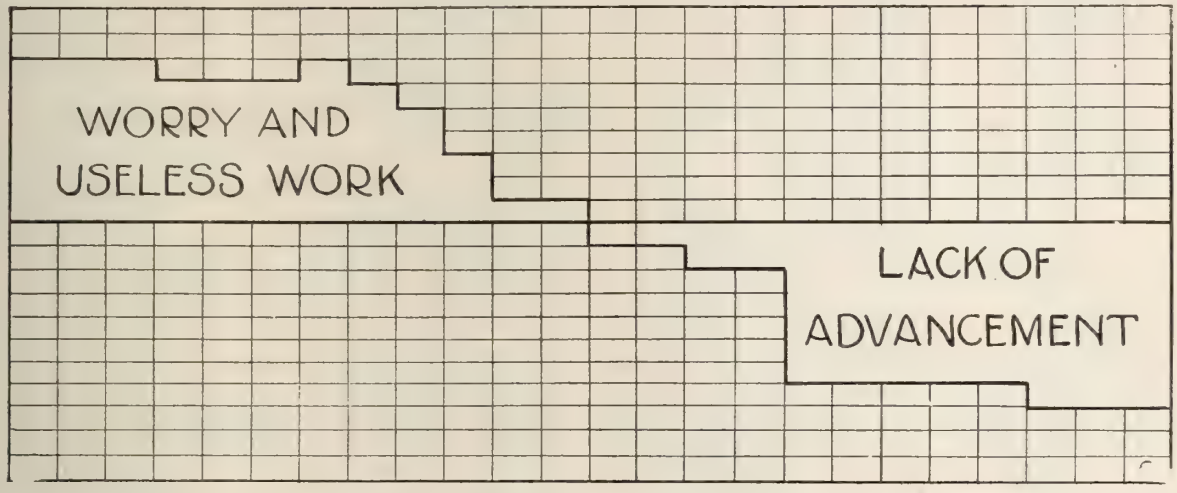
Let the *C.A.S.E.* Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

Canadian Association of Stationary Engineers

230 Caroline Street Hamilton, Ont.

Business Dry? Not Much!

DON'T you remember wondering, when you were a little Tad, what fun those great big chaps of twenty or so had? They didn't go "bobbing"—they didn't spin tops. Then you remember, perhaps, how, at twenty or so you rather pitied the old fellows of thirty-five or fifty who didn't dance (in those days) or do anything much.

But now, at thirty-five, fifty, or even sixty, you find there is plenty of interest in life. The form of fun may change, perhaps the ideas of what constitutes fun—but fun, interest, there still is.

Business is Rightly Called a Game

Business is the interest—the fun—for many of us. We enjoy playing ourselves and we enjoy reading about the play of others.

This is why THE FINANCIAL POST, dealing with business, is bright, entertaining, a welcome week-end guest in some eight thousand homes.

Consider some of the articles in a recent issue:

A sketch of George Sumner, the newly appointed head of Montreal's Board of Trade—a man who is at work every day at 8 a.m., but who has found time to become an expert photographer and art critic. Peter McArthur's new suit—dealing with the farmer writer's boasted purchase of an all wool suit for $45; speaking of the comparative value of this with one he could have bought prior to the war, and showing what he would have to pay for each in eggs and wheat.

A $4,000,000 stock offering coming for new movie chain.

Canada proposes to pick and choose her immigrants.

The Financial Post Editorials Have a Kick Behind Them

"Marse" Henry Watterson, the famous Democrat Editor, tells in his reminiscences of being criticized for himself criticizing the Democrat party. Marse Henry replied in his paper by quoting:

"Things have come to a hell of a pass
when a man can't wallop his own jackass."

THE FINANCIAL POST is willing to wallop anything—but it doesn't wallop just for the fun of walloping. It wallops to achieve something.

Consider Some Recent Editorials:

"Give Drury a Chance"

An editorial describing the "sniping" by the daily press at the farmer Government—admitting certain mistakes of inexperience but calling for fair play; instancing how J. K. L. Ross, heir to many millions, was put, by his father, in a position where he could make mistakes in order that he might win through to success.

"Foolish Defiance of Canadian Law"

A scoring of the Fort Francis Pulp & Paper Company for refusal to admit the sheriff, and in other ways prejudicing the public against the pulp and paper industry as a whole.

S. R. Parsons Now Butts Into Insurance

An editorial telling of the Canadian Manufacturers' Association's mutual insurance schemes which went wrong, and pleading for a big man to manage the C.M.A. "The most useful and necessary institution in all Canada."

There's life in each issue of THE FINANCIAL POST. It will help you keep informed on important financial and business matters. It is a paper for the leaders of thought in each community, be they rich or not. Fill in and send to us the attached coupon. Annual Subscription $3.00.

SUBSCRIPTION PRICE $3.00 PER YEAR (52 ISSUES)

D
Plibrico is easily moulded to fit any place.

PLIBRICO Keeps the Heat Where It Belongs

PLIBRICO keeps the heat in the furnace, because it forms a jointless, one-piece lining in your front door arches, entire fronts, side walls, arches, bridge walls, etc. This lining is gas and air-tight, saves fuel while at the same time greatly reduces your furnace upkeep, will last longer, give better satisfaction and can be more easily repaired than a lining constructed of fire brick or fire clay.

PLIBRICO is also unexcelled for baffle construction and repairs.

Write for book on furnace building.

JOINTLESS FIRE BRICK CO.

Offices and Factory, 1130-1150 Clay St., Chicago, Ill.

Beveridge Paper Co., Ltd., Montreal. Shell Bar Boico, Supply Co., Ltd., Toronto. Canadian Representatives.

Shipped in steel containers only. Warehouse stock carried in principal cities for immediate delivery.

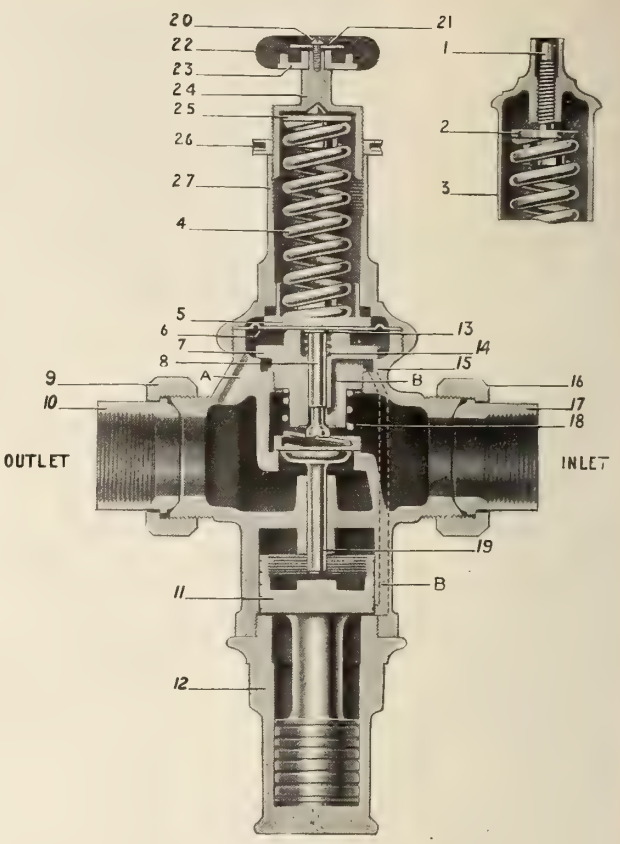
MORRISON'S

J.M.T.

solves the problem

Since the appearance of this valve there has been no "problem" of pressure reduction of steam and air. The J.M.T. valve does all that a pressure reducing valve can do. **A sudden change in the low pressure demand, or variations in flow and pressure on the high pressure side have no effect on the even, low pressure maintained.** Safety and dependability are fundamental features. Made in sizes and with reduction ranges to suit every requirement, and sold with the well-known Morrison guarantee.



METHOD OF OPERATION

J.M.T. Reducing Valves are controlled by the variation of the reduced pressure acting through the port A, (shown in the cross-section) on the diaphragm 6. This diaphragm is resisted by the spring 4, which is adjusted to the desired pressure. This construction allows the diaphragm to be raised by an increase of the reduced pressure and forced down by the spring 4, when the reduced pressure is decreased. In use the diaphragm is balanced between these two forces, the slightest change of reduced pressure causing a movement of the diaphragm.

The auxiliary valve 8 is held in contact with the diaphragm by the auxiliary valve spring 14, and moves up and down freely with the diaphragm. As soon as valve 8 is open steam passes through into port B and under piston 11. By raising piston 11 main valve 19 opens against the initial pressure, because the area of valve 19 is only one-half of the area of piston 11, steam is thus admitted to the system. When the pressure on the low pressure side reaches the required point, which is determined by the spring 4, the diaphragm is forced upward by the low pressure steam which passes up through the port A to the under side of the diaphragm 6, allowing valve 8 to close, shutting off steam from piston 11. Main valve 19 is now forced to its seat by the initial pressure, shutting off steam from the system and pushing piston 11 down to the bottom of its stroke. Steam beneath piston 11 exhausts freely around the piston (which is fitted loosely for this purpose) and passes off into the low pressure side.

In practice the main valve does not open or close entirely with each slight variation of pressure, but assumes a position which furnishes just sufficient steam to maintain the desired pressure. Piston 11 is fitted with dash pot 12, which prevents chattering or pounding.

These valves can be furnished for ranges of reduced pressure as follows: 5 to 50 lbs., 50 to 140 lbs., 140 to 300 lbs.

Each valve when shipped from our factory has a tag attached stating the range of reduced pressures for which the diaphragm spring is suited. For other pressures a suitable spring will be furnished.

Note—Diaphragm spring 4 is the only one in the valve that needs to be changed to obtain the different ranges of reduced pressures.

Magnified Strength

TRADE PENBERTHY MARK.

BE SURE THIS NAME IS ON THE VALVE YOU BUY

Penberthy valves are **NOT** just ordinary valves. The feature of "the outside bonnet construction" (see cut above), will convince you of that fact. This feature is a modern progressive idea of the **correct** way to **MAKE** a valve **SAFE** and **RELIABLE.** It is not found in the ordinary valve which has not kept pace with new and practical ideas of valve construction.

When you examine the careful and painstaking workmanship and finish of every part of the valve you are also convinced of the fact that "Quality First" **IS FIRST** in the minds of the makers of Penberthy brass valves.

PUTS AIR TO WORK

BURN LESS AND CHEAPER FUEL

HAVE you given the same careful consideration to the operating cost of your boiler room as you have to the other departments of your plant? Because the boiler room does not come under your eye as frequently as the financial statement does is not a fair reason for letting it run day in and day out without giving it some consideration. To-day no one item of expense affects your profit and loss account more than the coal bill.

There is enough coal for you, not the kind you usually buy perhaps, but enough of cheaper grades, like hard coal screenings, to keep the boilers working. Your stack may not draw well enough to burn this cheaper fuel but a

Sturtevant

MECHANICAL DRAFT SYSTEM

will. It will not only burn this cheaper coal while the present shortage exists but it will place you in a position to continue using this fuel year in and year out. The system pays for itself in actual fuel saving as well as making you independent of embarrassing shortages. These are not untested theories; they are facts, practically proven in many boiler plants using the Sturtevant System.

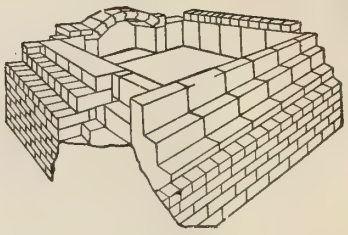
Reduce Your Boiler Room Upkeep

Gates Patent Arches and Furnace Linings

eliminate costly repairs. Their close-fitting joints offer no projections for the formation of clinkers—no possibility of costly air leaks.

Gates Arches and Furnace Linings are easily installed and are so designed that when any part becomes fused a handy man can replace them in half the time it takes to repair a standard firebrick job. Apart from the saving in time and labour and the elimination of continual Furnace repairs, your saving in fuel alone would soon pay for the installation of Gates Arches and Linings.



We specialize in all kinds of POWER PLANT BRICKWORK

Boiler setting, Furnace building and Oven work are our specialties. Our engineers are at your service. Call on them at any time for any information you may require — without obligation to you.

Reduce Your Overhead

THE proper use of selected lubricants is a sure means of reducing overhead expenses and of eliminating unnecessary operating costs. *Perfectly-lubricated machinery gets less wear and lasts longer.* Repair bills are smaller and fewer; depreciation is kept at the lowest possible figure when lubricants are chosen with an eye to mechanical needs and service conditions.

Imperial Lubricants are designed to meet definite needs and conditions. Made from the best crudes they are formulated and designed for real service. They are Canadian-made and readily obtainable everywhere in Canada through our extensive distribution system.

There is a "just right" grade of lubricant for each type of machinery and for each moving part—railroad, marine, power plant, factory and mill. The right use of Imperial Lubricants will reduce your overhead.

Imperial Lubrication Engineers are at your service for consultation. Their co-operation and recommendation for better lubrication are part of Imperial Oil Service.

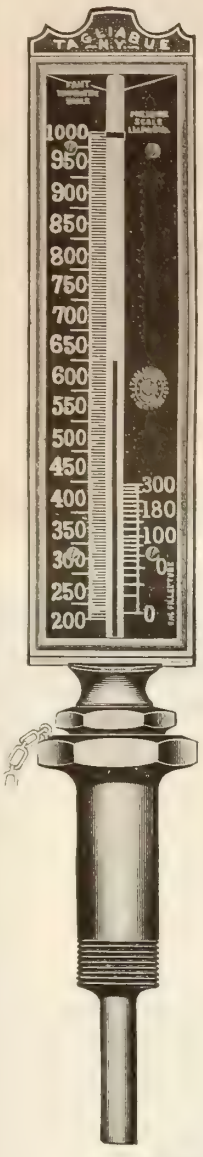
TAG

Thermometers for the Power Plant



Exact knowledge of the temperature in your steam pipe is necessary if a power plant is to be operated on the most economical basis. Inaccuracy in this respect leads to waste.

In the TAG line of Industrial Thermometers there is just the thermometer you need, made especially for the power plant.

Power plant Thermometers are illustrated and listed in our catalog PP-405, together with several other types of apparatus of interest to the engineer.

We'll see that you get this catalog if you will write us.

These Men are America's Leading Combustion Experts

Every step of the training has their careful censorship, giving you the fruits of their broad and successful experience.

Hays School of Combustion
1108 State-Lake Bldg.
Chicago, Ill.

Better Jobs— Bigger Salaries

Let These Men Show You How to Get Them

Are you interested in sure and rapid advancement to a really worth while position in one of the best paying professions in the country today? If you are it will pay you well to read this announcement. It tells how you, with or without previous training, can prepare yourself in a short time for an attractive position that insures a lucrative salary and an assured future.

Remember—this profession is a new one—unlike all others, it is still uncrowded—and the demand for trained men far exceeds the supply. That's why your services will be in demand when you have acquired the necessary training. That's why you can count every effort a sure and wonderfully profitable investment.

Easy to Learn— No Experience Necessary

In most professions, to become proficient, long periods of intensive study, followed by years of hard training, are necessary. In this new profession—Combustion Engineering—the necessary training can be acquired in a few short months. Why? Because all the knowledge and experience—all the scientific research and experiments—all the labor and study of seven of America's leading Combustion Engineers have been condensed and classified to such a remarkable extent that what formerly required years of study can now be learned in a fraction of that time.

This training from the very first can be applied to the practical every-day problems of any power plant. At some point in the course you must spend some time in power-plant work if you have not already had the experience. That may prove to be your field or you may make it the stepping stone to an executive position. In either case your services will increase in demand and value as you progress in the training.

America's Leading Combustion Engineers Teach You

On this page are photographs of our educational staff. Probably you know some of these men personally. At least, all or most of them, are known to you by reputation.

Jos. W. Hays is the author. His reputation as a writer on Combustion Efficiency is world wide. In this course he has surpassed himself. Every lesson, every chapter, is written in such an interesting, comprehensive way, that the reading of the course is as pleasant as it is profitable.

Associated with Mr. Hays as reviewing and advisory editors are **I. E. Moultrop, W. L. Abbott, Jos. Harrington, Fred R. Low, David Moffat Myers, Prof. S. W. Parr and Arthur L. Rice.** These names alone are proof positive of the thoroughness and completeness of the course.

Especial attention has been given to make this course easily understood by everyone. It is stripped of all unnecessary technicalities and is written in a way that you can quickly grasp and understand. It is prepared especially for the man on the job—the busy man in office or boiler room who can commence putting his knowledge into practice the moment he starts the course.

Send for this FREE BOOK—TODAY

To enable you to get a better idea of just what this course is—just what it covers—why it is a guide to a better job and a bigger salary—why it enables *you* to cash in on the big salary awards that fall to the Combustion Expert—to make all these things clear to you, we have prepared the book "Opportunities for the Combustion Expert." Send for a copy of this book today. It's free.

Mail the Coupon

Simply fill in the coupon and mail it to us. We'll send you a free copy of "Opportunities for the Combustion Expert" by return mail. Time is valuable. Get started today while the opportunities are greatest. Mail the coupon—Now.

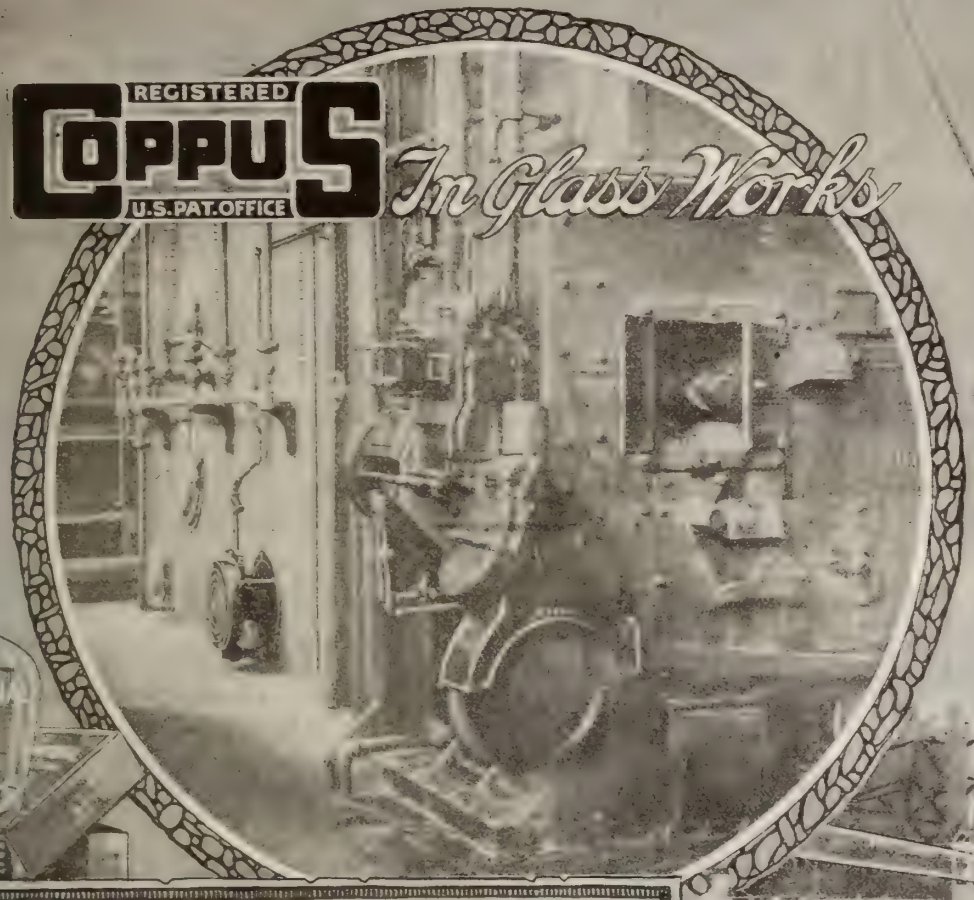
REGISTERED COPPUS U.S.PAT.OFFICE

In Glass Works



In the Glass Division Power Plant of the National Lamp Works out in Cleveland, Ohio, they burn gas coal screenings and producer tar—difficult fuel to burn economically. Yet with the 4-18" COPPUS Tubo Blowers which they operate, full steam pressure is maintained in their 4-250 H.P. Stirling Boilers—and cheap fuel is efficiently burned. Without these Blowers, one of which is shown above, additional boilers would have been necessary last fall. With their aid, however, the heavy plant load is easily handled.

Before the National Lamp Works installed COPPUS Blowers a careful investigation satisfied them that for efficient operation, low steam consumption, and sturdy dependability, COPPUS Blowers stand in a class by themselves. And after practical proof that COPPUS Blowers are all that is claimed for them, Mr. Bretz, Plant Superintendent, expresses himself as "highly pleased with them." In the National Lamp Works, as in thousands of plants in every industry, COPPUS Blowers have proved profitable investments.

Why not find out exactly how and why "COPPUS EQUIPMENT CAN SAVE YOU MONEY." Write us and our engineers will help you solve your combustion problems. If you haven't a copy of Blower Catalog write for one to-day.

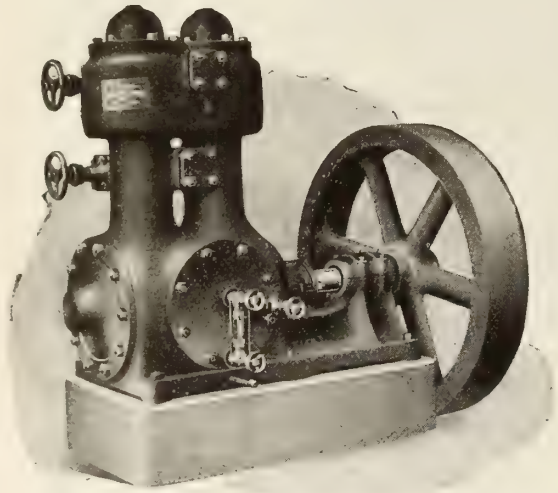
Mechanical Refrigeration



BETTER Than Ice

When saving in operating cost and saving in foodstuffs are taken into consideration, the superiority of **MECHANICAL REFRIGERATION** over refrigeration by ice is beyond comparison.

But any Refrigerating Plant, to be a success and, therefore, profitable to its owner, must be properly designed and installed to meet existing conditions.

Refrigerating installations by the York Organization are based on over 30 years' experience in building Refrigerating Machinery exclusively.

From the standpoint of service, economical operation, low upkeep cost and small amount of attention required, York Enclosed Refrigerating Machines are the best available.

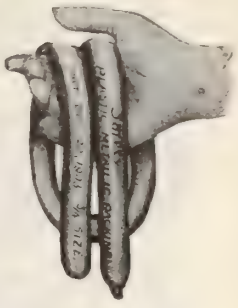
Practically Frictionless



In Cotton Tubes

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

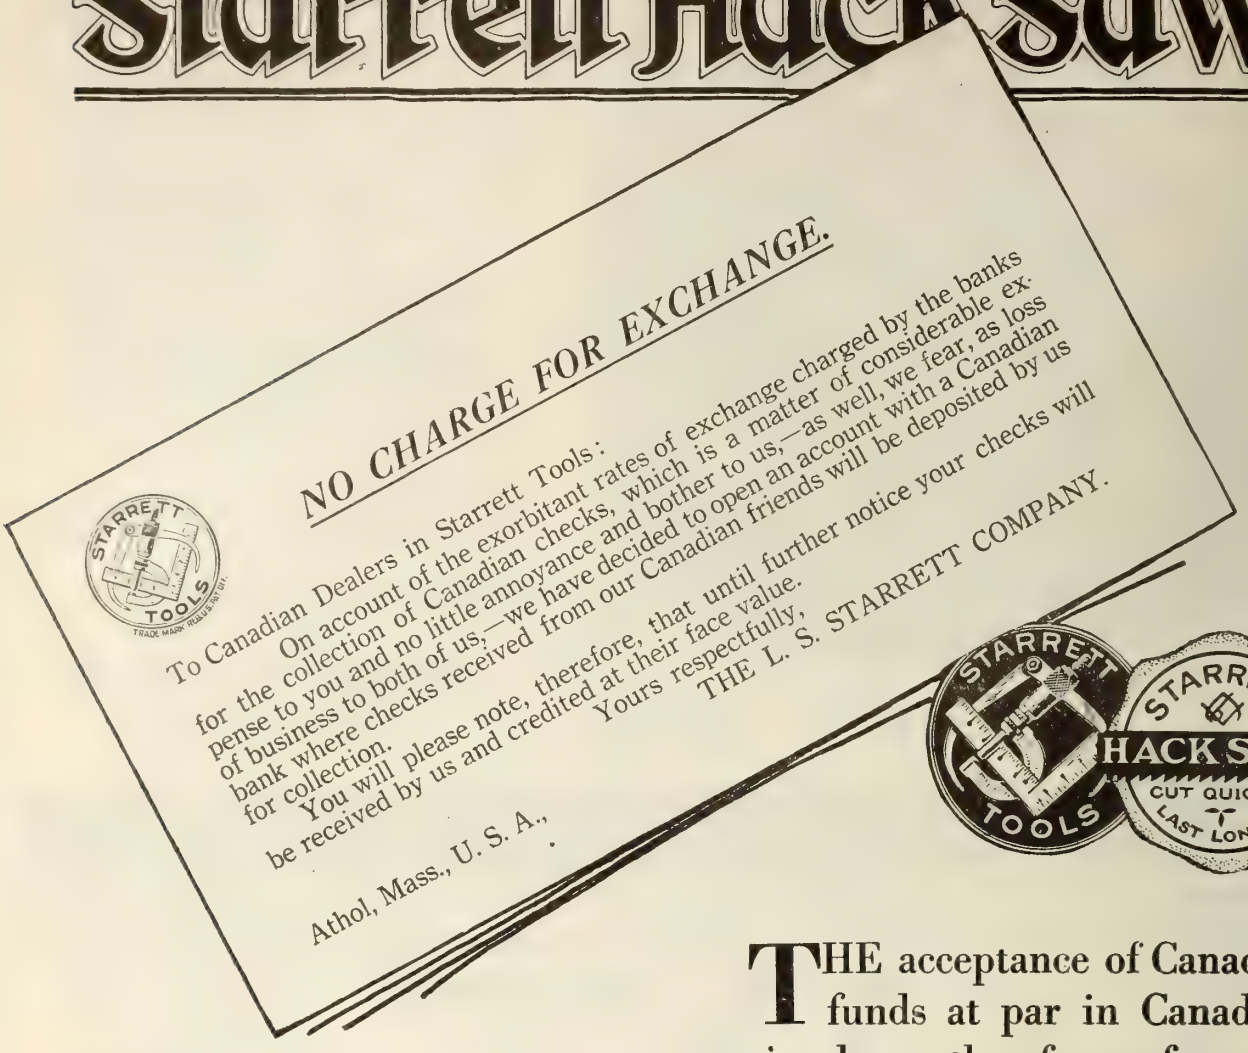
Starrett Hack Saws



NO CHARGE FOR EXCHANGE.
To Canadian Dealers in Starrett Tools:
On account of the exorbitant rates of exchange charged by the banks for the collection of Canadian checks, which is a matter of considerable expense to you and no little annoyance and bother to us,—as well, we fear, as loss of business to both of us,—we have decided to open an account with a Canadian bank where checks received from our Canadian friends will be deposited by us for collection.
You will please note, therefore, that until further notice your checks will be received by us and credited at their face value.
Yours respectfully,
THE L. S. STARRETT COMPANY.

WORTHINGTON "SNOW" OIL ENGINE

More Power from Less Fuel

Worthington "Snow" Oil Engines

WORTHINGTON "Snow" Oil Engines are of the high-compression cycle type. The heaviest and cheapest crude oils can be used as fuel without sacrifice of efficiency. And the consumption of fuel and lubricating oil ceases immediately when the engine is stopped.

These two features are desirable in all installations and are a necessity in those where additional power is required at short notice and where shut downs are at frequent intervals.

Longevity and durability are attained by reason of utter absence of sudden pressure changes and resultant freedom from knocks and pounds.

Worthington also manufactures a complete line of oil-line pumps.

Worthington "Snow" Engines may be used for any service where stationary power is required and are obtainable in single, twin, and three cylinder units, suitable to a variety of prime-mover purposes.

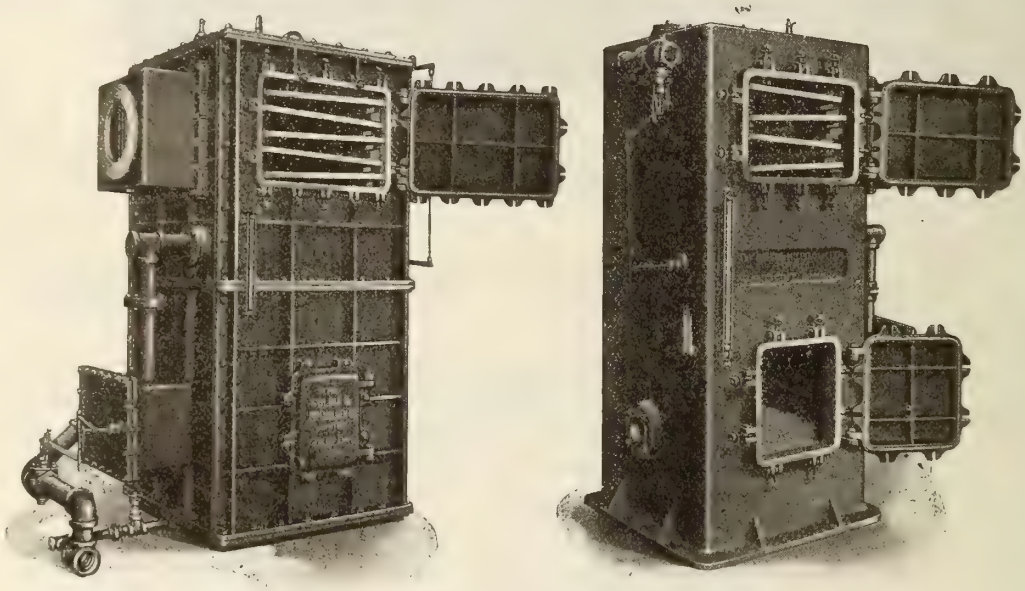
MODERN AND DEPENDABLE POWER EQUIPMENT



Showing the Sectional and Solid types of G. & McC. Cast Iron Open Feed Water Heaters.

The solid type is built in sizes up to 500 horse power, while the sectional type is built in sizes ranging from 600 to 5000 H.P.

They form a combination of Feed Water Heater, Purifier and Oil Extractor of the open or Exhaust Steam Type and will most effectively extract oil and grease from the exhaust steam.

They will deliver the feed water at almost boiling temperature and at the same time will take out any scale forming matter that can be precipitated at this temperature.

WE BUILD

STEAM ENGINES, STEAM TURBINES, RETURN TUBULAR AND WATER TUBE BOILERS, PUMPS, CONDENSERS, HEATERS, TANKS, STACKS, etc.

We can help you with your power problems, our catalogs and the advice of our Engineering Department will be sent free on request.

Re the Ontario Graded Certificate Act

Correspondence

Clearing Up a Misconception

THE following letter emphasizes the fact that the work carried on by the Board of Stationary Engineers and that by the Department of Education are entirely separate and distinct, and that the syllabus of instruction issued by the Department of Education for the use of its instructors is not an outline of the subjects to be learned, but only a guide to the instructors. The Editor.

Regarding the item headed "To Stationary Engineers," on page 98 of your issue of February 20th, the writer is quite in agreement with the editor in feeling that what is required at the present time is constructive rather than destructive criticism of the recent regulations respecting stationary engineers. If these regulations are too adversely criticized, it is possible the Government will feel we do not know what we do want, and will repeal these regulations, which would leave us as badly off as of old; but if we can point out practicable improvements which could be incorporated in these regulations and which would be of real value in licensing engineers, we will likely get the regulations amended in time to the satisfaction of the majority. In the meantime we should do nothing which would undo the good work which has been started, and we must remember that the Board of Examiners are human and will enforce the regulations with common sense and discretion.

Regarding the mention of the step which the Department of Education has taken to help engineers, there seems to have been some misunderstanding in this matter. It appears that this department of the Government has sent out to various night-class instructors a list of subjects which might be taught for the various grades of examinations, and some of these instructors have intimated to their classes that this list was sent out by the Government (not mentioning which department), and therefore must be the official syllabus of work required for the various examinations. When these classes have heard this and have seen the lists, they naturally conclude that the standard of the list is far too high and that too much is expected of them. The only official list so far sent out by the Board of Examiners, or the Department of Labor, is the 1919 copy of the regulations relating to the examination of engineers. Undoubtedly this is the cause of some of the adverse criticism we have seen and heard. Doubtless anyone who knew all the work outlined in the above syllabus would be able to pass the various examinations; but there is no doubt they will also pass knowing very much less than is outlined by the Education Department.

The instructors in the technical schools and night classes are practical engineers, and no doubt take THE POWER HOUSE, and will be greatly assisted in their work by reading the opinion of engineers on the kind of work that should be taught; but letters pointing out defects without suggesting remedies are useless to them.

There is much truth in the substance of the letter of "Justice II" in the above issue, viz: There are many engineers who believe themselves first-class, because they have operated for years without serious trouble, but who are really not all-round engineers and would be lost in case of trouble or if called on to handle any kind of work they had not done before. This is the class of men who constitute the majority of those who are afraid to try the examinations, or who think that first-class certificates should be granted without examination.

Personally I am of the opinion that the grading of plants should be more like that suggested by Mr. Noble in the above issue. Also in line with Mr. Stones' letter in the same issue, I feel that a practical engineer should not be required to memorize great quantities of technical information, but should know where to find that information and how to apply it to his work. This means that for the technical part of the examinations, especially the higher grades, he should be allowed to use approved handbooks, mathematical and steam tables, and mathematical instruments, as with the use of these he can save much time on examinations, which he can apply to the engineering features instead of working out areas of circles, etc., which he has probably been able to do since he was a boy.

CY. LINDER.

Is the Second-Grade Plant Too Small?

IN REPLYING to a suggestion offered in the March 5th issue of POWER HOUSE this correspondent misses the distinction between the first and other classes of certificate. The first grade examination is distinctly stated to be a highly technical one and of a theoretical nature. The requirements for this grade of engineer insofar as practical experience is concerned are met by the length of experience required. On the other hand, the lower grades of certificates are not of this nature, and any examination questions asked the applicant for them will be of a practical nature. For this reason it would seem that the purpose to be met is also different in the different grades. The first-grade man should, under the Act, be capable of design, inspection, and everything properly belonging to the consulting branch of the profession, while the second-class certificate is intended to apply to the operating engineer in particular and should ensure his competency for the position. Therefore the size of plant should be taken large enough to ensure his receiving fair and just treatment. The desirability of the first-class certificate should be affected in no way by a change in plant size requirements.

The questions asked are impossible of answer at the present time and will remain so until the Act comes fully into operation and the information is available. There are and will be no first-class engineers except those who pass examinations.

The Editor.

Sir—In your editorial note preceding the letter signed "Anonymous" you make the statement that 2,000 H.P. is a good standard for second-class engineer's certificate. Before I start my editorial warfare, I would like you to answer three questions, viz: (1) How many plants are there in the Province of Ontario from 2,000 H.P. upward? (2) How many first-class engineers are in favor of raising the requirements for second-class certificate? and (3) How many second-class engineers?

My reason for asking these questions are: If you raise the standard of the second-class certificate as suggested, you are taking away the ambition of many engineers to fight for the very much coveted first-class certificate. No doubt this assertion sounds rather vague, but weigh in the balance the number of plants above 2,000 H.P. and the number of first-class certificates, and I am afraid you will find the second-class engineer is in the majority. This does not leave any field for the first-class engineer to work in.

I would like to make a few remarks on the letter of our friend "Anonymous," but please ask him to come out in the open. The war is over and there is no further need for camouflage. He has my sympathy in his fight to try and be an engineer. I myself, since my apprentice days, have had some rough roads to travel; but, nothing venture, nothing win, and the peak of the hill came rather late in life. I grant that the board expect a lot for their money, but those men who framed the laws — surely they are men who understand the game. I dare venture to state that there is not an engineer in Ontario twelve months from date who won't know the questions and answers of the grade they wish to pass for, and it not only raises the status of the engineer, but compels him to learn something they never would have learned before. I only wish the Province of Quebec was just as difficult, although in the old days, before our present regime of absurdity was inaugurated, my examination for boiler inspector took me eight days' sittings at five hours a day. I don't wish to take up too much space; our friend, the editor, may call me to account; but I feel I must now make a few comments on all letters in POWER HOUSE during the seven years I have been a subscriber to POWER HOUSE. Quebec has been a myth in its pages. I am afraid I don't agree with "Anonymous" in saying it does not take any more trouble to look after a 1,000 H.P. than a 300 H.P. Please remember that as the H.P. grows so does the responsibility, and, I am afraid, in many cases so does the grey hairs. His remark on the meanness of employers extracting the limit: Please remember, employers don't employ us for charity. We are a necessary evil, and it behooves us to be as near perfect as possible. The employer knows the laws, pays the standard wage — or should do — therefore he should get the standard man. If he employs a man to take charge of his plant, with a lower certificate, take it for granted he is studying the financial end of it, and it is from such as these we look to our engineers' laws to protect us.

I am glad he is working under a good chief. We all like to work under a good man, and if they are well trained we can always sit at the master's feet and learn something day by day, which will fit us to be good men also when the time comes for us to take his place. Now, "Anonymous," be of good cheer; give our editor a chance to make good his word in the many articles he has promised us; and, please, study them, and you in time to come will say, "I never thought I could learn so much in so little time."

The old bone of contention comes to the fore again: The chief operating engineer versus the consulting engineer. I don't think all the highly competent engineers will be driven into the consulting field; that branch in a few years will be extinct, because in the years to come every competent chief engineer will be his own employer's consulting engineer. The majority of employers in times gone by had the wool pulled over their eyes by the high-sounding words and great promises of the college consulting engineer, and the poor chief engineer got wrinkles and many grey hairs trying to do what the consulting engineer said could be done, until the employer began to think quietly, and say to himself, "What is wrong?" and when he found out a vacancy occurred. Mind, I speak from experience. What the engineer of the future will have to do will simply be to prove to the employer that the consulting man is a negligible quantity around his plant. In some of my later letters I may deal with a few vagaries of these same benighted gentlemen.

Now, Mr. Editor, I hope I have not tried your patience too much by my wail from Quebec; but I am in the field for a good argument, and I am the man from Missouri, so please show me where I am wrong.

HENRY WRIGHT.

Graded Certificates Are Satisfactory

THE writer below is quite satisfied with the graded certificate and is of the opinion that it will eventually raise the standard of stationary engineering.

The Editor.

I have read with much interest the comments on the Act which have appeared in POWER HOUSE, and I am very much surprised at the fault some engineers have found with it. We all know that everything has to have a beginning, and I am sure it is a step in the right direction, as it places the engineer in various classes, which is only just. We all know that engineers are not all good, nor all poor, so the only fair way to get a proper distinction is to grade them.

When a man has followed the business for a number of years and then cannot measure up to the proper standard he should drop out of line and make room for the man that has qualified and made a study of his business. This latter man is the one who should be given first place. We all know men who, while holding a certificate, should be out on the farm instead of being in charge of a steam plant and it is to be hoped that the graded certificate will weed out some of this class of would-be engineers.

A READER.

Man's Memory is a Treacherous Thing

THE use of textbooks for examination purposes is deprecated, but the use of a list of formulæ, likely to be encountered, has many good features, according to Mr. Carmichael.

The Editor.

I have read the various letters published in your paper with much interest. There seems to be a good deal of objection to parts of the new Act, and I think it is to be expected. No such Act as this can be perfect at the start, and it will probably be some time before such imperfections can be ironed out by amendment. One prominent objection refers to the fact that all engineers have to write the examination for the first-class certificate, and some of them for the second also, the objection being that men who, although knowing their business from coal pile to exhaust, cannot remember formulæ and such as they used to do. Others say that men who are now holding first-class positions and have held them successfully, should be granted the first-class certificate. Still another group would like to be allowed to use the textbook at examinations.

Dealing with the last first: I have written examinations using textbooks and have found them of very little use. An examiner can easily set a paper in such a way that the textbook will be of little use. It leads to lost time, and besides he considers himself justified in setting the most difficult paper he can.

The second group certainly have right on their side, but if we grant these certificates where are we going to stop, and how are we going to stop the objections of those who have not been granted certificates? The easiest way is the examination, and I think by following my suggestions dealing with the first objection most of the opposition to the examination route will disappear. These are as follows:

Very few men can remember a string of formulæ and they should not be required to do so. If an engineer understands and can apply a formula and has the textbook, that is quite enough. There are a few formulæ which are used so frequently that they will always be remembered. Now, if on examination the candidate is given a sheet with all formulæ likely to be required, he should recognize any one of them as a casual acquaintance at least. This will do away with all the time lost looking for it in "the book," and a man's mind is not cluttered up with a lot of stuff better stored in its proper place.

The first-class examination will probably be difficult enough, anyway, but having passed it you have a certificate worth while and one which, like a university degree, gives you a certain standing anywhere.

A. D. CARMICHAEL.

What is a Wop?

THE writer, in a pleasant way, takes exception to Mr. Noble's definition of the untrained engineer, and points out that the man with only practical experience may yet consider his position in the engineering field as one of dignity.
The Editor.

The probability is that this letter may never be published, for various known reasons. Firstly, being an initial effort in this direction, it may appear too crude for insertion; and, again, like all its predecessors, it may never be sent. We shall hope for whatever seems best. The reason underlying this effort is that a certain umbrage has risen within me through a recent statement made by your very esteemed contributor, Mr. James Noble. This gentleman is convinced that any man who doesn't understand the theoretical or technical side of engineering is a mere "wop," or laborer. Sir, our dignity is outraged; our profession (God save the word) is betrayed. As a matter of fact, if his assertion is correct, then the majority of the plants in Ontario are run by "wops." I imagine that, to the greater number, the deciphering of mathematics or formulas is about as easy as the reading of, say an American newspaper. It would certainly be interesting to know where those details would be acquired. Certainly not in the little schools amongst the woods where the bulk of our present generation got the three R's castigated into them. Then, whereas mathematics may appear simple to those who have obtained the fundamental principles in their youth, they appear immensely difficult to acquire in late life. But I would suggest that is not the end. We have men in any quantity who are ignoramuses regarding those things, but who would be mighty hard to beat around engines or boilers. As a case in point, if we have that type of man — trustworthy, ingenious, and probably with a long and meritorious record — are we to classify those individuals in the category complained of? Sir, there are no "wops" in this line of work. They have a complete right to the designation of engineer, be it good, bad or indifferent. As may have probably been remarked, the lines of inconsistency are peculiar. In reference and as an illustration, a mere girl goes to an institution for a short time and emerges with the "dignity" of a graduate nurse. Or if you can cram a young fellow through his examinations from which he may probably emerge with the title of Doctor, after which he don't require to renew it every year, but can make his fortune if it's only by making up bottles of colored water with abbreviated Latin inscriptions on the labels (which are usually copied), or makes good money writing prescriptions for booze in favor of deserving patients suffering from thirst. Still, he's a doctor, mind. But for the man in charge of a plant with all its varying phases, its manifold worries and its never-ceasing vigilance, unless he have the gift of technical education there is no dignity in his calling. He remains for all time a mere "wop." Sir, this letter is long; it is probably wearisome; but I should like to see a few letters from the many wops in Ontario if it was only to show that, in spite of their manifold educative disadvantages, they could still say in relation to their jobs: "My foot is on my native heath — my name's Macgregor!" With apologies,

A "WOP."

The "Wop" Defined

THE word wop as applied to the engineering fraternity, or at least to a certain portion of it, has aroused some little resentment, and in this letter Mr. Noble defines his position and makes clear just what was meant by the use of the term.
The Editor.

For the information of Mr. Henry Wright, whose letter appears on page 102 of the March 5th issue of POWER HOUSE, you might print the following. His definition of the meaning of the word "wop" as a fool is altogether wrong.

A "wop" may be described as a man without ambition; a man who is so well satisfied with his present job that he has no wish or desire to go any higher. He may be a man who is too careless or too lazy to study. He may have a quart of brains under his hair, but lacks the energy to work them any more than absolutely necessary to earn enough coin to buy food and a few other essentials.

He may be a man who believes that his own small amount of one lifetime's experiences equals that of thousands who have put their experiences into print, primarily to earn some good money, principally because they have a whole-hearted wish to help others who may not have had their particular experience. Therefore a wop is a wop.

Mr. Wright is somewhat inconsistent in his expressions. He mentions a splendid (does this mean an efficient and capable man, or does it refer to his character?) mechanical engineer absolutely devoid of technical education. I fail to understand how any man can be an engineer, either directing, designing, erecting, operating, consulting or assisting, or any other kind, without some technical knowledge. I can assure Mr. Wright that I have considerable technical and practical knowledge, and have yet to see the man who has too much of these things in combination.

Mr. Wright states that the majority of engineers do not take the trouble to study. I expect he is referring to the men in the Province of Quebec. If he had visited as many engineers in Ontario power plants as I have he would remark that the majority of engineers — in fact, every one of them — do study theory to a considerable extent. After talking with some hundreds of Ontario engineers I have failed to find one of them very much lacking in technical knowledge.

Further along in his letter Mr. Wright states: There is no chief worth a row of pins if he has not considerable technical knowledge. If Mr. Wright finds amusement in the troubles of the Ontario engineers who have a very difficult examination confronting them, his idea of amusement is different from mine. Some of our engineers may have difficulty in putting their thoughts clearly into writing, but they deserve credit for having the nerve to try. Believe me, the Engineers' Examining Board in Ontario will see that the law is carried out, no matter what their private opinion may be. It will not be "scamped," as it apparently is in Quebec Province, according to Mr. Wright's letter. Your correspondent does not believe in allowing second or third-class men to handle plants larger than the average cheese factory outfit. He should consider that in this Province large plants can not be handled by men with fourth-class papers, or no papers at all, as is done in Quebec, according to his information. I infer from his letter that he is up in years. I am in the same position, but we should consider the young fellows. If they are not encouraged to look ahead to a chief's position in a few years, they are apt to drop into a rut, or drop out of the engineering game altogether — in fact, become "wops" so far as engineering is concerned.

JAMES E. NOBLE.

The Crossley Cold Starting Oil Engine

This Engine Has the Advantages of the Diesel Engine as Regards Fuel Consumption and Starting Up From Cold and Also Possesses Other Advantages Not Shared by the Diesel Type—We Are Indebted to "Motor Ship and Motor Boat" for the Following

NOTHING is more satisfactory at the present time than the number of new features that are being introduced in the design of oil engines, and the completely novel types of motor which are in some cases being constructed. Generally speaking, users and many engineers are not fully aware of the importance of the changes being made, and particularly in one direction, in which what might almost be termed a revolution is being effected. This lies in the development of an oil engine which shall have the advantages of the Diesel engine as regards fuel consumption and starting up from cold, and shall, moreover, be a simpler type, costing less to build and being easier to run, whilst still being able to utilize any fuel which can be satisfactorily burned in a Diesel engine.

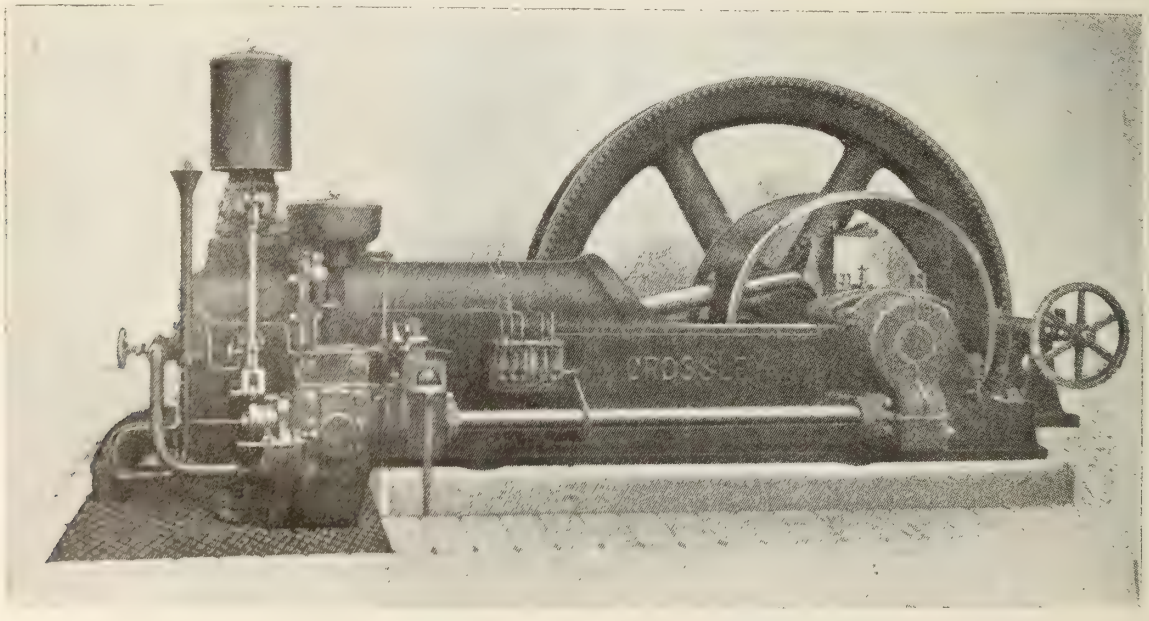
It may be asked how these advantages can be attained, for it is clear that if they are attained, the new type of engine becomes an extremely serious competitor to the Diesel motor. The answer is that by taking an ordinary oil engine of the four-cycle type of which so many thousands have been built by various manufacturers in this country, fitting a specially-designed combustion chamber (in which very efficient mixing of the fuel with the air gives perfect combustion), and increasing the compression pressure of this motor to a reasonable extent, it will be possible to produce an engine with all the advantages just outlined.

It need hardly be said that this new development will have a very important influence upon marine oil engine construction, and particularly from the point of view that the cost of manufacture will be largely reduced. The type is now being built on a large and standardized scale of production by Messrs. Crossley Bros., of Manchester, for stationary work, and although the motor which we are about to describe is of the ordinary horizontal land design, the manufacturers now have under consideration several sizes of marine engines for which producer gas and crude oil will be used. Exactly the same features will be incorporated in the engines as those which are now being dealt with in the stationary motor, and all the principles of operation will remain unaltered. We therefore make no excuse for describing an essentially stationary set, and hope at no distant date to give fuller details of the first marine engine built by this well-known firm.

It is interesting to know that Messrs. Crossley's first attempts at ignition by heat of compression were made as early as 1905, when an engine was constructed on these lines with an entirely water-jacketed combustion chamber, and in which the oil was injected directly into the water-jacketed combustion chamber by means of a cam operated pump and without the aid of injection air. The difficulty in those days was to obtain sufficient power and sufficiently clean working with residual oils to make the engine a commercial article. As Mr. Webb, their chief engineer, put it, we flirted outrageously at times with all kinds and combinations of methods of fuel spraying, governing, compression, turbulence, combustion chambers,, etc. (especially the etc.), but it was some years before all the details began to be perfected and the way made clear to obtaining high power, clean running, cold starting, low compression, simplicity and fool-proof parts and, above everything, reliable automatic working under all conditions.

The new engine was satisfactorily passing from the experimental into the manufacturing stage when the war broke out. The delay in production caused thereby was utilized still further to develop the principles on which the engine was built, and to put in hand designs and patterns for larger sizes.

The Crossley oil engines are made under the Crossley-Webb patents and are constructed for use with refined, crude and residual petroleum oils and with tar oils. They are of the four-cycle type, and are manufactured in various sizes from 10 b.h.p. to 130 b.h.p. per cylinder. The following description applies to all sizes except in minor particulars. The illustrations, which are taken from the drawings of the engine which was tested and reported on last year by Professor Burstall, are slightly modified so as to show as many points as possible in each figure. This engine had a cylinder bore of 18.5 ins. and a



EXTERNAL VIEW OF 130 H. P. CROSSLEY ENGINE

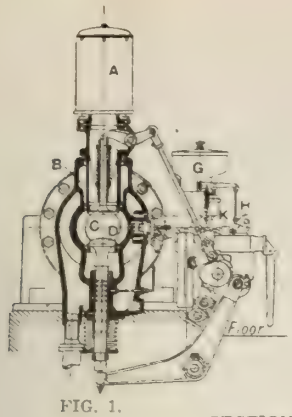


FIG. 1.

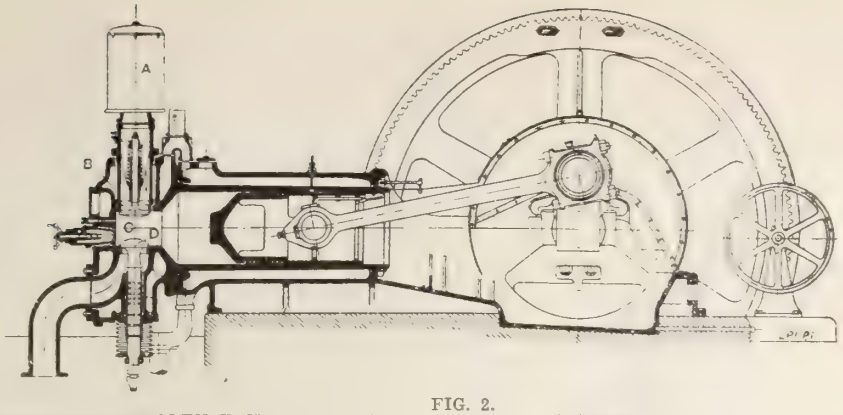

FIG. 2.

SECTIONS THROUGH CROSSLEY FOUR-CYCLE COLD STARTING ENGINE

stroke of 28 ins. and developed its normal load of 117 b.h.p. at 180 revolutions per minute.

Fig. 1 represents an end elevation of the engine in section through the combustion chamber. Fig. 2 is a front elevation of the engine in section through the cylinder. Fig. 3 illustrates the oil pump and oil control details, while Fig. 4 shows the construction of the oil heater as used for viscous oils. Figs. 5, 6 and 7 illustrate certain physical actions in the combustion chamber, and Fig. 8 is a reproduction from a photograph of the engine.

The engine works on the four-stroke cycle. On the suction stroke of the piston air is drawn through the air silencer (A), air valve (B) and combustion chamber (C) into the cylinder. Towards the end of the compression stroke of the piston, when the bulk of the air has been compressed in the combustion chamber (C) a charge of atomized fuel is injected by a pump (J) through the oil sprayer (E) into the compressed and heated air in the combustion chamber, where it is ignited and burned, the resulting increase in pressure driving the piston forward on the power stroke. The exhaust valve (D) then opens, and the burnt charge is driven out of the cylinder on the exhaust stroke of the piston, when the cycle of operation recommences.

Three extremely important operations, which are more of a physical than mechanical nature, take place in rapid succession during the cycle. These are illustrated by means of sketches in Figs. 5, 6 and 7.

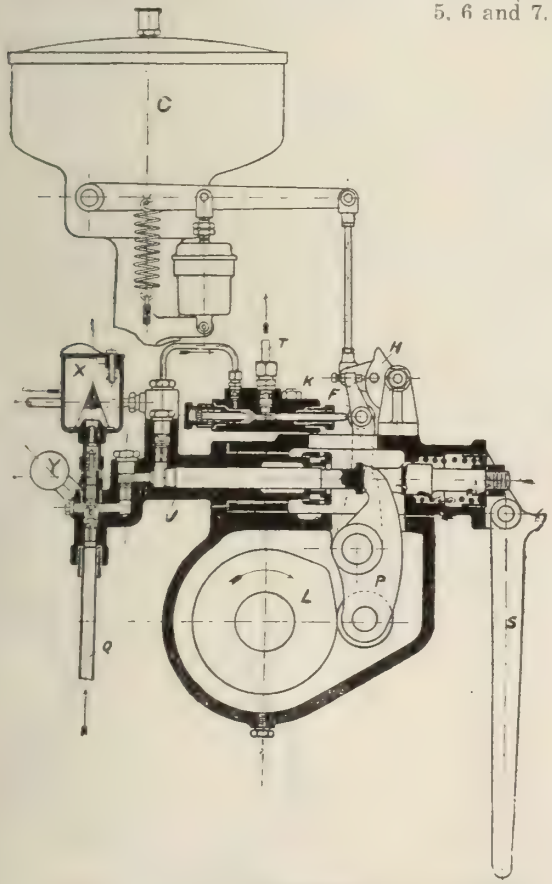

FIG. 3—PUMP MECHANISM AND GOVERNOR.

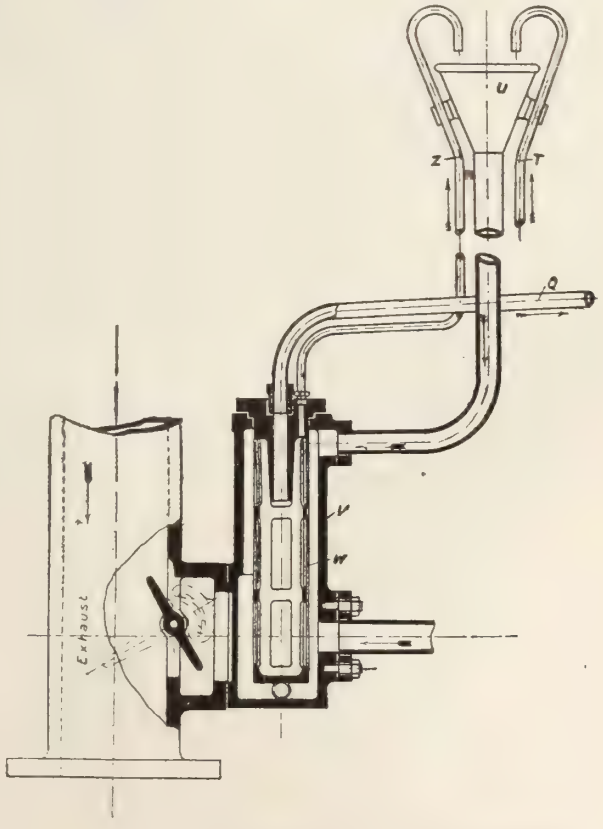

FIG. 4—DETAILS OF FUEL HEATER

1. The first of these three operations to note is the very complete scavenge of the burnt products which is effected in the well-known Crossley Atkinson manner which was introduced by the firm nearly 30 years ago. This scavenging action, which is illustrated in Fig. 5, takes place at the end of the exhaust stroke, when both the air admission and exhaust valves are open and when the inertia effects of the column of exhaust gases, passing out along the exhaust pipe, not only increases the volume of air in the combustion chamber but its cooling action also increases the weight of the contained air, thus enabling the engine to work on a cooler cycle and enabling a greater overload to be obtained.

2. The second of the three operations concerns the patent combustion chamber. It will be noticed that when the piston is at the end of the compression stroke the combustion chamber is very compact and concentrates the great bulk of the air in a very dense mass. This mass of hot compressed air is somewhat elongated in the direction in which the

oil is sprayed, the distance from the side of the combustion chamber whence the oil is sprayed to the extreme opposite side, as shown in Fig. 6, being greater than the distance across the combustion chamber. This is intentional and is done with the object of counter-

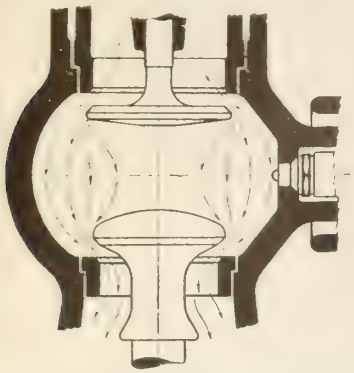

FIG. 5—ARRANGEMENT OF COMBUSTION CHAMBER AND EXHAUST AND INLET VALVES.

ing the tendency of the sprayed oil to cool the central zone of the air mass where the temperature is naturally greater. By making the chamber somewhat elongated the hottest zone of the compressed and heated mass of air is moved from the centre of the chamber to a point somewhat further from the sprayer, as indicated by a dotted circle in Figs. 6 and 7. It is claimed that this enables the degree of compression to be somewhat reduced (which is, of course, a very desirable feature) without impairing the efficiency of the engine. This claim appears to be fully justified by the fact that the engines can be started from the cold state with a compression of about 260 lbs. per square inch, which is quite a remarkable performance.

We ourselves saw the single-cylinder 117 b.h.p. engine described above started from the cold state, within a few seconds of giving the order, with compressed air at only 150 lb. pressure and from an air receiver of only 10 cubic ft. capacity. After three or four ignitions, from paraffin injected by the pump automatically, the fuel was immediately changed over to residual oil. After running for a few minutes the engine was stopped and was then restarted with residual oil (instead of paraffin) the pressure in the air received being 120 lb. per square inch.

3. The third of the three physical operations is that of the patented method of creating turbulence during combustion. It will be noticed that when the spraying of the oil into the combustion chamber is in full blast the projection or plug, shown on the end of the piston, enters the combustion chamber, as illustrated on Fig. 7, and the imprisoned air in the cylinder is forced through the space between the plug and the chamber walls, thus creating considerable turbulence in the chamber and having a marked effect in improving the processes of vaporizing the oil, of mixing the fuel with the air, and of burning the mixture. It will be noticed that the turbulence takes place mainly in the neighborhood of the walls of the chamber and that the hot "zone" is intentionally less affected until after ignition takes place.

We have dealt at considerable length with the effect of the special shape of the combustion chamber and the piston head, as we believe it is largely due to the design of this part of the engine that the somewhat remarkable results can be achieved. In our opinion, too little attention has hitherto been paid to the question of the correct design of combustion chambers in all types of oil engines, including hot-bulb and Diesel motors, and some of the poor results, both from the point of view of operation and fuel economy, that have been met with in the past, are, we feel, undoubtedly due to defective design of combustion chambers. This is more particularly the case in regard to Diesel engines in which the system of solid injection is employed, and if designers paid more attention to this point, it is possible that better results would be achieved with this system.

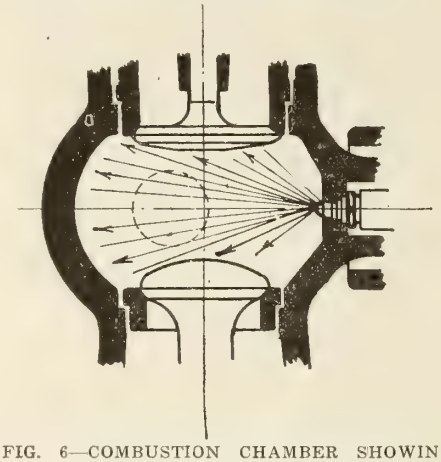

FIG. 6—COMBUSTION CHAMBER SHOWING ACTION OF FUEL UPON ENTRY.

The patent fuel pump and governor gear are particularly interesting. The plunger of the fuel pump (J) is actuated by the lever (P) from the cam (L) on the layshaft, the oil, which is drawn from the pipe (Q), being supplied to the spray valve through the pipe shown. In order to vary the amount of fuel supplied according to the requirements of the engine, part of it is by-passed through the by-pass valve (K), the amount so by-passed being controlled by the governor (G). The opening of the control valve (K) is effected through the floating lever (F), which is pivoted at its bottom end to the lever (P), operating the pump. It will be noticed that at the upper end of the floating lever it rests against a quadrant (H), which is shaped like a cam, and the position of which, relative to the floating lever is controlled by the governor (G) through vertical and horizontal levers. As the governor balls rise and fall therefore, the upper end of the lever (F) is moved to and fro, thus altering the position of the control valve plunger. When the pump plunger is actuated by the cam (L), the upper end of the floating lever becomes the fulcrum, and, the position of this being shifted by the governor, the control valve is opened at variable times, according to the load and speed of the engine.

The hand lever (S) is for priming the pump with oil before starting, whilst the cup (X) is filled with paraffin for use when starting up on cold mornings, a very small quantity of this fuel being necessary. The lever (Y) is merely a change-over lever, which allows the fuel to be drawn from the cup (X) instead of from the supply pipe (Q). Before the oil fuel passes to the fuel pump, it is taken through an oil heater, heated by means of the exhaust gases. The amount of heat can be varied by means of the butterfly valve seen in the illustration, and if no heat is required, as is frequently the case with certain oils, the exhaust gas passes straight through without impinging upon the heater. This heater is fitted with a vent pipe at the top (Z) in case the heating causes vapour to form, and there is a large strainer (W) for straining the oil.

It should have been added in connection with the description of the oil pump that the oil fuel which is by-passed through the control valve instead of passing to the spray valve is directed back to the tundish (U), and thence to the oil heater. The advantage of this is that the oil flow can always be seen, thus showing the attendant that the pump and governor are operating freely.

The starting air valve is located right at the back of the cylinder, as seen in Fig. 2, and when shutting down the engine, a screw valve is opened in the oil delivery pipe between the fuel pump and the spray valve. The whole of the oil is then delivered to the tundish so that the supply to the engine stops, and it consequently shuts down.

Comparison of the New Engine with a Diesel Motor

The fuel consumption of a 117 h.p. oil engine of this type, as tested by Professor Burstall recently, was only 0.425 lb. per b.h.p. when using residual oil with a calorific value of 18,000 B.Th.U. per lb.

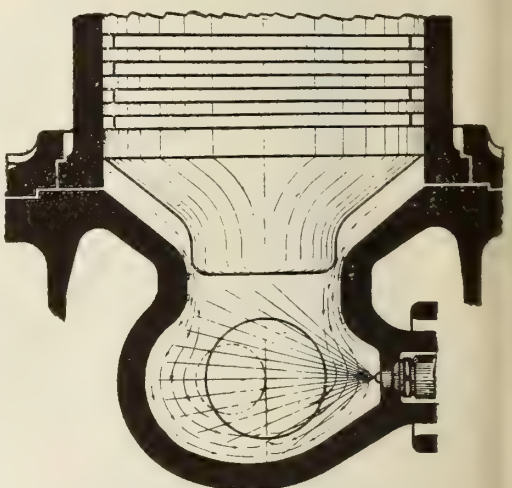

FIG. 7—COMBUSTION CHAMBER AND PISTON—SHOWING WHIRLING EFFECT CAUSED BY SHAPE OF PISTON.

The manufacturers claim the following advantages for the new Crossley oil engine as compared with the Diesel motor:

1. The maximum pressure possible in the engine cylinder is 700 lbs. against 1,700 lb. per sq. in. These are, of course, abnormal pressures.

2. The scantlings are much lighter.

3. The general design is simpler, being more simple than a gas engine and producer plant.

4. There are fewer possibilities of danger.

5. Any ordinary mechanic or intelligent unskilled man can run the engine.

6. The mechanical efficiency is 85 per cent. against 75 per cent. of the Diesel.

7. The first cost is 35 per cent. less than that of a Diesel engine.

8. The weight per b.h.p. is 25 per cent. less than the Diesel engine.

9. Accessibility is superior.

10. Lubrication is less complicated.

11. No hand regulation is necessary.

Whatever Diesel engine builders may say in objection to these claims, it is clear that the new type of engine is one which is bound to have a considerable influence on the future of the marine oil engine industry, and in particular the lowness in first cost is of the utmost importance.

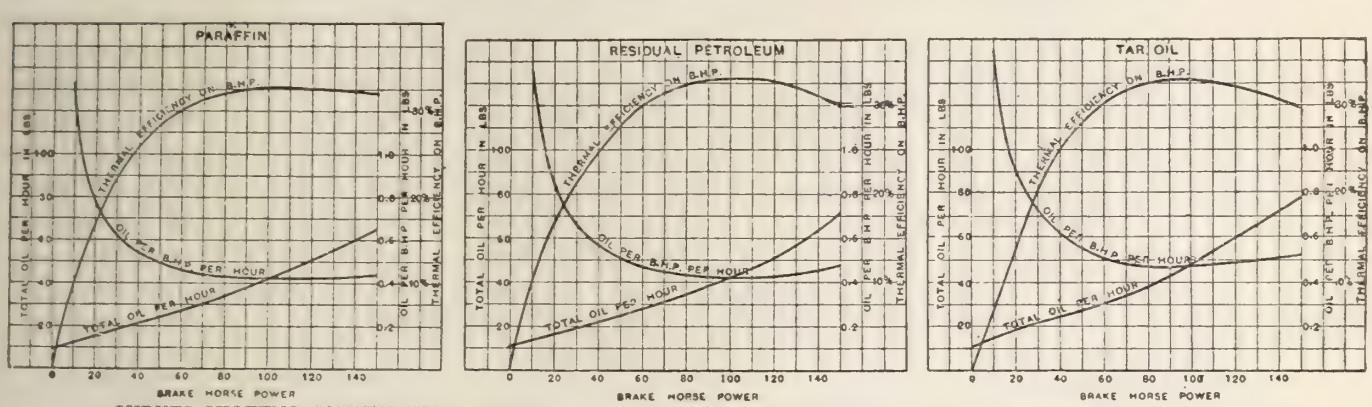
FILL UP THE BRIGHT OR THIN SPOTS

As the fuel does not burn at the same rate over the entire grate, thin spots will develop in any fuel bed. This difference in rate of combustion may be due to clinker, caking of the coal or difference in the sizes of coal.

The fireman should place the fresh coal on these thin or bright spots rather than cover the entire fuel bed. By doing so he will be able to keep the fuel bed level with little raking or poking.

NEW CATALOGUE

The James Morrison Brass Manufacturing Co., Toronto, have just issued catalogue No. 60, dealing with valves, fittings, and engineering supplies and specialties. The products of this firm are well-known to the steam, the heating and sanitary engineer, and the scope of materials and lines carried is shown in this catalogue. In its preparation The James Morrison Company have endeavored to include all the lines possible with details applying to each, in order that it may prove a complete and useful reference book for the trades in whose interests it has been issued. The standard catalogue size as defined by the Purchasing Agents Association has been closely adhered to and the convenient size of the book will be of much aid to its use.



CURVES SHOWING CONSUMPTION OF NEW 117 B. H. P. CROSSLEY ENGINE WITH VARIOUS FUELS.

THERMOMETER

By Walter L. Thompson.

3500	6330	Temperature of electric arc.
3500	6330	Carbon vaporizer.
3000	5400	Temperature attained by thermit.
2800	5072	Oxyacetylene flame.
2500	4532	Oxmium melts.
2225	4037	Iridium melts.
2231	4000	Heat in Bessemer furnace.
1710	3080	Platinum melts.
1530	2731	Wrought iron melts.
1400	2552	White heat.
1371	2500	Steel melts.
1200	2192	Orange red heat.
1100	2012	Copper melts.
1063	1981	Pure gold melts.
1050	1922	Cast iron (lowest) melts.
970	1778	Silver melts.
700	1292	Dull red heat.
625	1157	Aluminum melts.
405	762	(About) Coal ignites.
400	752	Red hot iron visible in dark.
357	674	Mercury boils.
316	600	Lead melts.
288	550	Gunpowder ignites.
215	420	Tin melts.
109	228	Sulphur melts.
100	212	Water boils.
79	174	Alcohol boils.
65	149	Fusible alloy melts.
61	142	Beeswax melts.
46	114	Paraffin melts.
44	111	Phosphorus melts.
36.8	98	Human body in health.
17	62	Mean temperature of sea.
10	50	Mean temperature of air (London).
0	32	Water freezes.
17.7	0	Mixture salt and ice.
38.8	34.3	Mercury freezes.
55	68	Greatest natural cold on earth. (Ant).
70	94	Balloon (9 miles high).
191	312	Air liquifier under normal pressure.
252	422	Hydrogen liquifies.
257	432	Hydrogen freezes.
260	436	Greatest art. cold produced by Devor.
278	49	Absolute zero.

REGULATE DRAFT BY DAMPER IN UPTAKE

Combustion or burning of coal is a chemical process in which the combustible combines with the oxygen of the air.

In order to have combustion it is necessary that a certain temperature known as the kindling temperature be reached and maintained. A fire is kindled to raise the temperature to this point; after the fire is started the heat produced by the combustion of the fuel maintains the temperature, and combustion continues as long as the proper amounts of fuel and air are supplied.

Combustion is an exact process; that is in order to burn one pound of a combustible, a certain definite quantity of oxygen is required, and a definite amount of heat is produced.

Since the oxygen required for combustion is obtained from the air, provision is made for controlling the admission of air to the fire so that the quantity can be regulated to suit the furnace conditions.

This regulation should be secured by the manipulation of the damper in the uptake or breeching, the damper being opened to increase the draft and allow larger quantities of air to enter when it is necessary to burn large amounts of fuel, and closed to cut down the draft when the demand for a heavy fire has ceased. The draft should not be regulated by opening the fire doors or by closing the ash pit doors. If the fire doors are opened the furnace is cooled off by the inrush of large quantities of excess air and heat is wasted. Closing the ash pit doors, of course, decreases the amount of air through the fire, but may also cause over-heating of the grates, and fusing of the ash on the grates into clinker. Another bad effect of closing the ash pit doors to cut the draft, without closing the uptake damper, is that excess air is drawn into the furnace through cracks in the walls or other openings in the setting.

The Khang; a Comparison Between Old and New

The Fuel Problem is One Which Concerns All of Us in Greater or Less Degree and While English Civilization May Think Itself Advanced, It Has Something Yet to Learn, Particularly as Regards Domestic Heating

By PADUS

SOME thirteen or fourteen years ago, a miners' strike in the United States, served as an excuse at least, for an increase in the price of anthracite coal to the consumer, and in particular to the Canadian consumer. I happened to know something of the conditions in the coal fields at that time, and my gorge rose at the thought, that I as a Canadian was to be compelled to pay a part of the cost of an American "Barons' and Peasants' War." I decided to stop buying American anthracite coal. It turned out to be something of a contract. I found a substitute, both cheap and effective, in gas coke, but neither cook nor furnace man, would use it, except under compulsion, and I am free to confess domestic calamities followed, and ructions were frequent and free, I persisted, and in the end no difficulty whatever was experienced in burning gas coke in an ordinary kitchen range and hot water furnace, and while it made in use more dirt than anthracite would have, it was an economical and a satisfactory domestic fuel.

Under these circumstances I was lead to give a good deal of attention to this question of domestic heating, and a great deal that the war scarcity has produced as new, is a very old story to me.

For instance "briquette," the patent fuel of the bunkers. Ten or twelve years ago, I reported on a briquetting plant and scheme for briquetting anthracite dust. The culm banks of the Pennsylvania coal region were to be purchased for a song, ground up, briquetted and turned into coal, at a four hundred per cent. profit. There was no doubt about the culm banks, in many instances they were owing to their size and position, limiting coal production, and the operators were being compelled to spend their profits in removing them. They were not made up of pure coal by any means, and had to be concentrated before they could be used. Then, after spending good money, in grinding, concentrating, binding, briquetting and handling, the product seemed to burn all right in a stove intendede to burn anthracite; up to the point where the briquette fell down in a mass of red hot dust. "Fuel consumption" stopped at this point, and gas production began. My crowd pulled out of the scheme, then and there, and I heard nothing more of it until I bought half a ton of briquettes a year or two ago, because nothing else was available, and the first night of frost, the old furnace resolved itself into a gas producer, the pipes froze, and as I couldn't buy coal, coke, peat or dry wood, I relapsed into a shelf dweller in a tabloid house or heated apartment for the winter. It would be more comfortable to hibernate, and I often wish that we had the secret of H. G. Wells' men in the moon, who put their surplus labour into cold storage, during "off time." My view of the matter is, however, that the strike, the war, etc., are not the cause of the coal scarcity. They are merely accidents that drive home the fact that the highly concentrated cheaply mineral anthracite coal deposits of the "valley" are becoming exhausted, and that these coals are no longer economical to waste, as domestic fuels. It is absurd to call the ordinary method of disposing of this almost ideal fuel, its use.

No other people ever had such a treasure, as the anthracite coal deposits of the "valley," and it has been squandered; as the white pine was squandered, as the virgin loam of the prairies is now being squandered, as the equally beautiful bituminous cooking coals are being largely squandered, and as a legacy this coal is leaving us the habits acquired in squandering it. Was it Mulvaney who asked: "Did you ever have a devil of a time and not have to pay for it Sor." The people of the winter snow regions of North America, have had a well nigh natural fuel to have a "devil of a time" with and now they will have to pay.

With ample supplies of Pennsylvania anthracite it was comparatively easy to design heating stoves and furnaces, that would keep up a continuous heat with comparatively little attention, and this was the end desired. That these appliances developed but a fraction of the heat giving resources of the fuel was a minor matter; the greatly desired thing was, that the fire should not go out, that the furnace could be kept stowed away in a corner of the celler, and the heat distributed by hot water or steam pipes, so as to produce the maximum effect in dehydrating the air in all the rooms of the house. Then, when the occupants of the aforesaid rooms felt a chill as the result of being in their turn dehydrated, the furnace draft was opened, more coal was thrown on the fire, more water was dried out of the air, more taken out of the unfortunates who breathed the air, and so on, until when the heat became unbearable, the drafts were all shut off the unhappy furnace The blazing anthracite not being allowed to get oxygen enough to produce C.O.2 produced C.O., and the resultant explosion was quite exciting, and furnished the society editor with paragraphs.

Of course, explosions did not take place every day, but the waste of coal never stopped, and even now that the cost of this waste has become apparent, it will not be stopped until about the time the coal has all been consumed.

On the American continent within the winter snow belt, the basis of domestic heating, is the slow combustion of fuel a continuous fire.

On the continent of Europe from the Rhine eastward to the Pacific, the basis of domestic heating is the Khang. The fuel is burned in such a way, that a large mass of non-conducting material is kept continuously heated.

In America we use a live coal, in Europe and Asia they use a hot brick.

The American method is based entirely on the anthracite coal of the valley; the most perfect of natural fuels. The European-Asia method uses anything that will burn, Legnite, peat, wood, brush, trash. The fuel of Seoul, the capital of Corea was pine brush.

I am inclined to think that the Khang in the form of the porcelain or soap stone stove of the North German Baltic-Scandinavian region, was much more likely to produce truly comfortable homes than the base burner or hot water furnace of North America, and it is an infinitely more economical contrivance. I am free to confess, however, that I have suffered more from cold in Scotland than I ever did anywhere else, (and I have been north of the timber line), but then, the British Islanders, had enromous resources in the most beautiful of cooking coal to waste, and if in North America we made a fetish of the radiator, in the British Isles, they made the "open fire place" an altar of Mollock, and sacrificed the immature, the weak and the aged thereon.

To add insult to injury is proverbially, to go the limit. The coal waste was surely injury enough, but when I think of how the Yankee bragged about his furnace, and the Britisher his open fire, I regret yet once again, I know not Arabic and have not the power of words to do justice to the occasion.

This is all very interesting, and to know and appreciate your neighbor's weakness and gaucheries, is almost as satisfactory as being the only man at the dining table in the saloon, the night you leave Belle Isle astern, but what are we going to do about it?

Tabloid houses, heated apartments for sooth, the conversion of a free man and a house holder into a shelf dweller, is not a remedy, it is simply shirking the disagreeable duty of tacking the problem

face to face, and it is only a solution for that very small portion of the population that can pay to be allowed to shirk.

Theoretically if tabloid houses could be built on a large enough scale to permit of the use of high pressure steam, mechanical stokers, and all the fuel economies of a good power plant, the city dweller could be kept warm economically enough, but this is a practical impossibility. In Glasgow or Edinboro, civic communities which have a common good and a civic conscience it might be tried but to think even, of such utopias in Montreal or New York, Toronto or Chicago, is out of the question.

We talk of the "stone age," and the cave dwellers. It will be lucky if our age is not called the "silly age" when men burned raw coal. The solution of all fuel trouble, is in the destructive distillations of coal in the mine, and it is not absolutely impossible that it would pay now. It certainly will in the near future. If all coal was "stilled" in the mine, the mine waste would be largely saved, the cost of mining reduced materially, and the products, gas, coke, tars, would be put to economical uses, not wasted as they now are. At present, it costs $2. to make, deliver and get paid for, a volume of gas-X, and the by-products are worth $1.00. The two dollars includes freight to the gas companies' plant, the up-keep of the gas distributing system, and the retailing expenses. If the gas works were at the foot of a mine shaft, it is quite possible, that the entire cost of distillation would be less than the value of the by-products, and the gas could be used for producing electric power that would compete with hydro power. It is quite possible, that the coal which now cannot produre economically ,the power, bunker fuel, domestic fuel, and by-products we require, would, if distilled, provide all these wants, (the bunker fuel in the form of oil) and the power would cost nothing, but its conversion into electricity at the mine heads. It is evident, however, that this system must be first tried out in a country like Great Britain or Belgium, where the distances are short, and there is a ready market for everything, power coke, bunker oil, chemicals, etc., in the vicinity of the mines, rather than in Canada where the coal is at the two ends of "the same fishing rods."

Up to the present, Canada's fuel problem has been that of New England, the winter snow region of America has been one unit, with no regard for frontier lines, but it is quite possible this must end, that the United States can no longer be relied upon for a supply of winter's fuel, and if exchange goes on falling, that the money to pay for American coal can no longer be supplied. There is Canadian coal in plenty, but it is concentrated on the Eastern and Western seaboard, and it is mainly a bituminous coal. The freight cost of supplying the coal required by Canada East of the Great Lakes from Nova Scotia, and Canada West of the Lakes from the Pacific, would be enormous, and the domestic use of raw bituminous coal present many difficulties. It would be necessary to redesign all the stoves and heating furnaces in the country, and if this must be done, it would pay to do more, to alter entirely the basis on which fuel is burned.

A great deal of wood is burned in Canada to this day, and the "'Khang" is coming into use, in a way. It is becoming quite a common thing in the rural districts to move the "big stove" into the cellar, and build a brick chamber about it, from which air pipes carry heated air to the different rooms of the house. The dirt from the stove is kept out of the house-wife's sight by this scheme, and although the brick work is generally used, as a substitute for metal work, because a metal worker is not available, still the heat is stored in the brick work while the fire is on, and given off when the fire is out. If this crude brick enclosure were developed into the "checker work" of the regenerative furnace, there would seem to be no reason why enough heat could be stored in the brick work of a furnace during the day, to keep any ordinary house comfortably warm during the night, and to prevent even the most severe frost from penetrating it. It certainly would if half as much attention was given to the heat insulation of the roof and the juncture between the earth and the building as is given to less important matters, double doors and porches for instance.

Such an appliance if in general use, would make for great economy in the use of wood as fuel.

The waste of the hard coal measures of North America has been prodigious, but hardly as great or as pitiful as the waste of hard wood. There is to-day a melancholy reminder of this waste in every creek or river that "runs red" with soil when in flood. The timber was chopped and burnt from the side of hills, and now, the water is washing the loam from these side rills to the sea, and the fertility of half a continent is being wasted.

I have before me a specification for cord wood and the hardwood forest of two counties in Ontario, were chopped to this specification in the fifties and sixties. Listen to this:

"All wood must be split from the body of the tree, to average 4 in. from scrap to point, no stick to be of unreasonable size, must be free from all crooked, crotched or knotty sticks, and cut from growing trees."

This means that about seventy-five per cent. of the wood growing on the chopped area would be left on the ground to be burnt for ashes. The cause for the specification was, of course, the desire to obtain fuel that would burn through the night. The cost of transportation was so great also, that it could only "pay" to haul the very best wood. I have burned a great deal of wood, and my judgment is, that there is little or no difference between branch and body wood or between poplar and hard maple. If the moisture content is the same, you get about as much heat per ton of wood, no matter what the wood is. A ton of poplar is very much more bulky than a ton of maple, as a matter of course.

If "Khang" the hot brick, were used instead of the iron stove, the live coal, for continuous heating, the quicker the flame, the more heat would be thrown into the brick, and it would be possible to use, faggots brush wood, straw, even for domestic heating.

The large house would require a system of heat distribution, but hot bricks will keep hot as well as hot iron, and the hot water could distribute the heat through the house, while in the smaller ouse the hot bricks would directly warm the air of the inhabited rooms.

It would appear therefore, that the "Khang" offers the most immediate and most available method of meeting the domestic fuel problem.

It would enable bituminous fuel to be burned with fair economy, or, at least with about the same degree of economy that is now obtained in power production, and that is an enormous advance on the ordinary house furnace practice of the day. If the under-feed grate is adapted, as it should be, the economy of fuel would be considerable. I have carefully considered the possibility of using powdered fuel. It would pay, but it would be practically impossible to devise an automatic fool-proof method of feeding coal dust in a small scale. There are no mechanical reasons, however, why the under-feed principal should not be applied to the modified Khang indicated.

It would make it posible to use wood, wood refuse, brush wood and straw for domestic heating, with economy and no loss of comfort.

It would make it possible to use wood, intelligent grappling with this question of domestic heating in all its bearings, and might lead to further developments.

Since Rumford's time there has been practically no attempt made by scientific investigation and research to improve our domestic apparatus, and Rumford's lessons have been completely forgotten.

I cannot close without pointing out that to burn wood raw is just as wasteful as to burn coal raw, wood distilled gives a great variety of useful products, and charcoal properly used is an ideal household fuel. A block of 300 miles square of Laurentian country would furnish Canada with all the fuel, she now buys in the form of hard coal, forever, and an enormous quantity of exportable chemicals, wood oils, etc.

HOW IT HAPPENED

Once a year the newsboys of a certain district of London are taken for an outing up the Thames by a gentleman of the neighborhood, when they can bathe to their hearts' content.

As one little boy was getting into the water a friend observed, "I say, Bill, ain't yer dirty!"

"Yes," replied Bill. "I missed the train larst year."

Autogenous Welding and the Steam Boiler

Some Examples of Fire Box Sheet Failures Are Given, Together With the Rules of the Steam Boiler and Fly Wheel Service Bureau

By T. H. FENNER, Associate Editor

AUTOGENOUS welding which has made such wonderful strides in recent years, has sometimes suffered severe set backs through wrong applications. By this we mean applications to jobs which were not suited for this particular method of repair. The failure of these repairs has destroyed the confidence of many people in the process itself, and has led to many unfair judgments. Autogenous welding, in which is included both the oxyacetylene and the electric arc process, is an excellent thing in itself, and has performed some wonderful work, cheaply and quickly. It has a field of usefulness in the steam power plant, but its limitations are better known now than formerly. A definite set of rules has been laid down governing the application of welding in boiler repair work, and should be carefully studied by all power plant engineers and owners. These are printed in full herewith, and should be kept on file for reference in case repairs of the nature mentioned should be necessary. These rules have been compiled by the Steam Boiler and Fly Wheel Service Bureau, New York, an organization which includes engineering staffs of all the large insurance companies on the North American continent.

Rules of the Steam Boiler and Fly Wheel Service Bureau

By "autogenous welding" is meant any form of welding by fusion, that is, where the metal of the parts to be joined or added metal used for the purpose is melted and flowed together to form the weld. Such welding is accomplished by the oxy-acetylene, hydrogen or other flame processes, or by the electric arc; no distinction is made between any of these processes. The general rule to govern the acceptance of such welds in insured vessels is that prescribed by the Boiler Code of the American Society of Mechanical Engineers, Par. 186, as follows:

"Autogenous welding may be used in boilers in cases where the strain is carried by other construction which conforms to the requirements of the Code, and where the safety of the structure is not dependent upon the strength of the welds."

FIG. 4—ANOTHER LOW WATER EXPLOSION IN WHICH TWO PERSONS WERE KILLED.

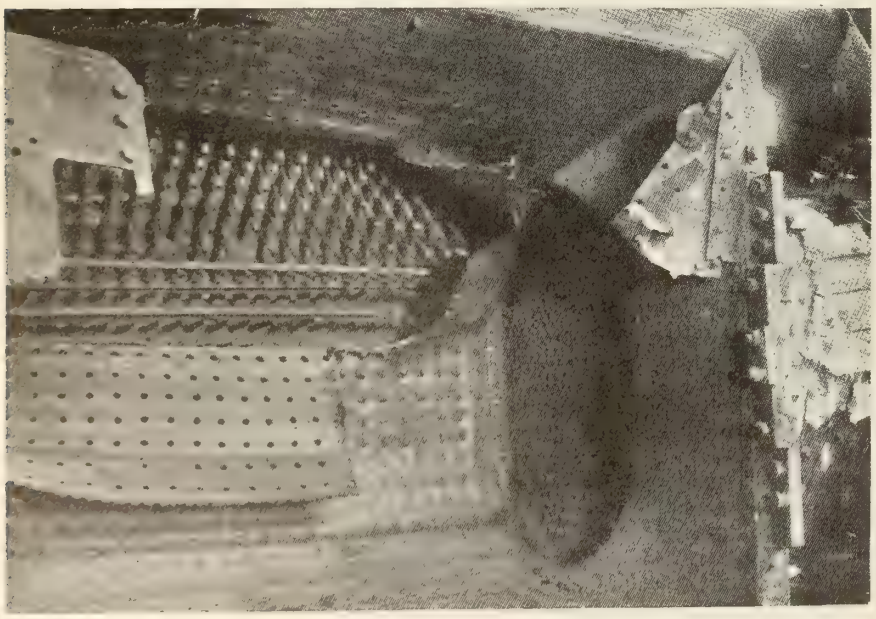


FIG. 1—RESULTS OF EXPLOSION CAUSED BY LOW WATER, IN WHICH THE WELDED SEAM BETWEEN THE CROWN AND SIDE SHEETS GAVE WAY.

The following illustrations will serve to point out where such work should be accepted or rejected.

1. Any autogenous weld of reasonable length will be permitted in a staybolted surface or one adequately stayed by other means so that should the weld fail, the parts would be held together by the stays. It is necessary for the inspector to use judgment in interpreting the meaning of "reasonable length" as given above, since it may vary in different cases. In the average case it should be not more than 3 ft. Autogenous welding will not be accepted in unsupported surface.

2. The edges of the inner and outer sheets of vertical firebox boilers or boilers of the locomotive type may be joined by autogenous welding to form the door openings, if the surrounding surfaces are thoroughly stayed. This would also apply to other openings of a similar character in such surfaces.

3. For low pressure, plate steel boilers operated at a pressure not exceeding 15 lbs. to the square inch, or for higher pressure in unfired vessels subjected to water pressure only, rectangular headers may be autogenously welded at the edges if the sheets are properly held together by stays. Autogenous welding of cracks

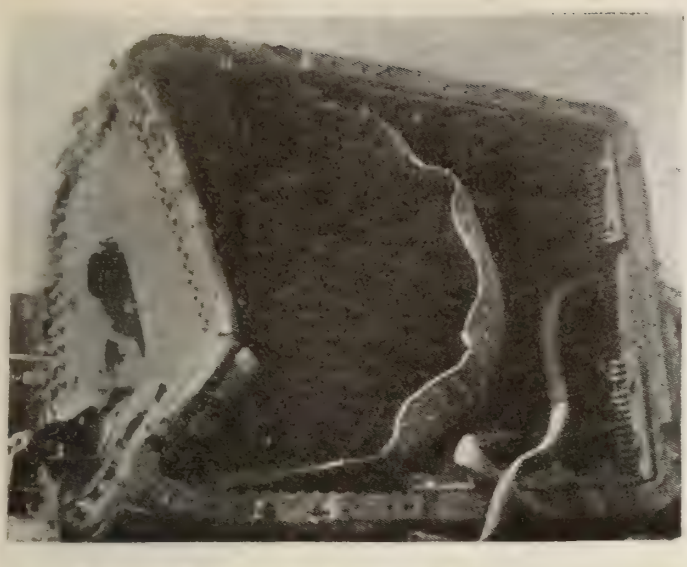

FIG. 2—FIREBOX INTERIOR SHOWING THE GENERAL CONDITION AFTER A LOW WATER EXPLOSION.

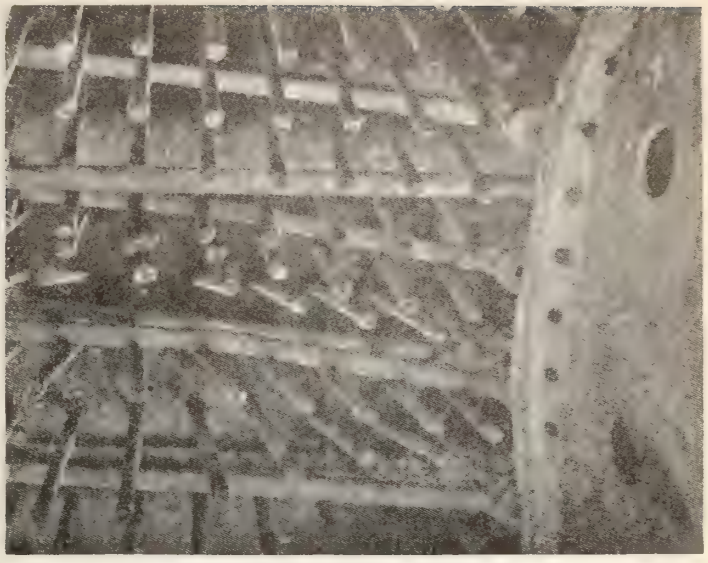

FIG. 3 THE BACK HEAD WAS STRIPPED AWAY FROM THE STAYBOLTS IN THE OVERHEATED AREA.

and fractures in cast iron boilers will not be permitted.

4. Fire cracks in girth seams extending from the edge of the plate to the rivet hole may be autogenously welded provided the cracks are properly prepaired by cutting out the metal at the crack in the form of a letter "V" to permit fusion through the entire thickness of the plates.

Similar cracks in girth seams located between the rivet holes may also be autogenously welded, provided the cracks do not extend beyond the edge of the lap of the inner plate. In the

FIG. 5—FIVE RIVETS AT LEFT END OF CROWN SHEET HELD WHILE WELDED PORTION FAILED.

latter class of cracks it is advisable to drill a hole not exceeding ⅜ in.. diameter at the end of the crack before the weld is made. Cracks extending from rivet hole to rivet hole on girth seams cannot be welded. the edge of the hole, the plate may be built up by autogenous welding under the following conditions: The original section of the metal between rivet holes and calking edge to be built up must average equivalent to ¼ of the diameter of the rivet hole and the portion of calking edge to be replaced must not exceed 30 in. in length in a girthwise direction. In all repairs to girth seams by autogenous welding the rivets must be removed over the portions to be welded and for a distance of at least 6 in. at each and beyond such portions. After repairs are made the rivet holes should be seamed before the rivets are redriven.

5. Stayed sheets which have corroded to a depth of not more than 40 per cent. of their original thickness, may be reinforced or built up by autogenous welding. In such cases the stays shall come completely through the reinforcing metal so as to be plainly visible to the inspector.

6. Where tubes enter flat surfaces and the tube sheets have been corroded or where cracks exist between the tube ligaments, autogenous welding may be used to reinforce or repair such defects. The ends of such tubes may be autogenously welded to the tube sheets. The above-mentioned repairs for tube sheets and the welding in of tubes in the sheets are not to be permitted where such sheets form the shell of a drum or boiler such as in the case of Stirling type of boiler.

7. When external corrosion has reduced the thickness of plate around handholes to not more than 50 per cent. of the original thickenss and for a distance not exceeding 2 inches from the edge of the hole, the plate may be built up by autogenous welding.

8. Pipe lines will be accepted where the flanges or other connections have been welded autotenously, provided the work has been performed by a reputable manufacturer and the parts properly annealed before being placed in position. Such welding when made with the part in place and un-annealed will not be acceptable.

9. Autogenous welding in patches in the shell of a boiler will not be

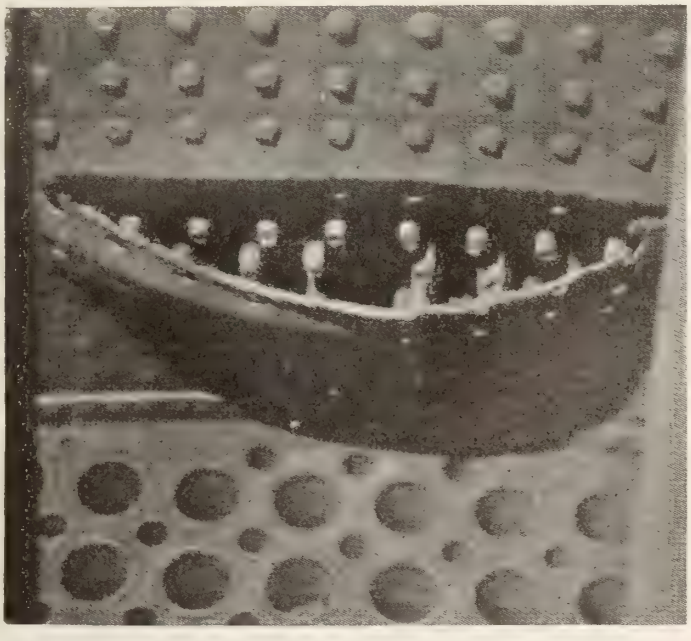

FIG. 9—FAILURE OF CROWN SHEET AT WELDED SEAM.

acceptable regardless of the size of such patches. Autogenous welding of cracks in the shell of a boiler—except those specified in Par. 4—regardless of the direction in which they may lie will not be permitted, unless such welding is only for the purpose of securing tightness and the stresses on the part i fully cared for by properly riveted—on patches or straps placed over the weld. The plates at the ends of joints may be welded together for tightness, provided the straps or other construction is ample to care for the stresses on the parts so welded.

10. Re-ending or piecing of tubes for either fire tube or water tube boilers by the autogenous process will not be permitted.

In connection with the above, we have before us the report of the Chief inspector of the Locomotive Inspection Bureau of the U.S., which contains some illuminating instances of boiler failures. The fact is brought out strongly that in the case of boiler explosions in boilers containing welded seams, 80 per cent. of these welds failed. The conclusion drawn by the chief inspector is that until the quality and tenacity of such welds can be determined in advance of their failure, they should be avoided in seams that are liable to be overheated.

An instance of the explosion of a locomotive boiler which blew up killing three people, is given. The locomotive at the time was hauling a freight train, and the force of the eplosion threw the boiler 165 feet ahead, where it rebounded and landed 230 feet from the scene of the accident.

The firebox was a new one, having been installed just two months previous to the accident. It was of the semi wide radial stayed type, the crown sheet supported by button lead radial stays pitched 4 x 4 inches. Side and crown sheets were of one-piece construction, door and flue seams being welded autogenously, without any riveting. The only riveted seams were those on the mud ring. The water at the time of the accidents was five inches below the highest point of the firebox crown sheet. The front end of the crown sheet, being three inches higher than the back end, would of necessity receive the most overheating, and would have supposedly failed first. However, it was the crown sheet seam that failed. The investigation was carried out by two Government inspectors, assisted by an assistant chief inspector, and their unanimous opinion was that the explosion was greatly intensified by the failure of the welded seam.

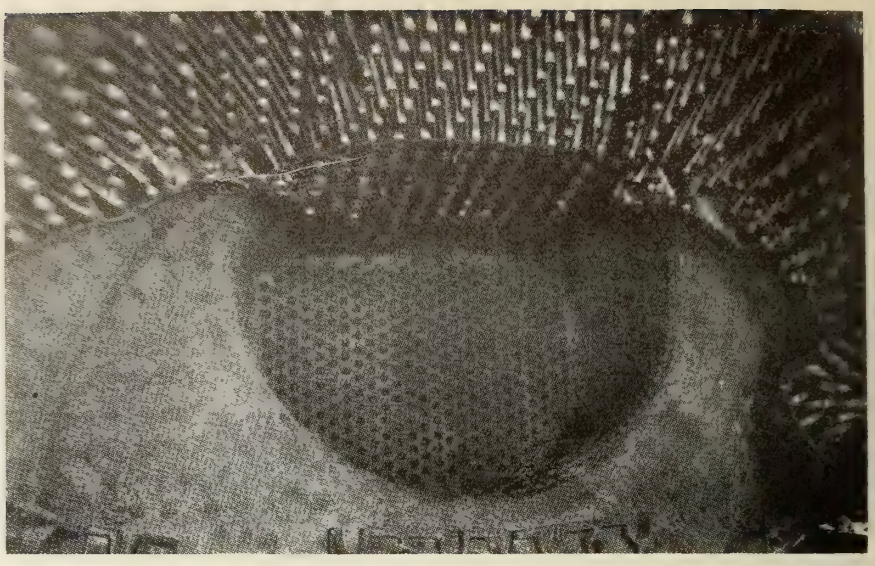

FIG. 6 WELDED SEAM IN CROWN SHEET FAILED IN THIS EXPLOSION WHILE RIVETED SEAM AT THE TUBE SHEET REMAINED INTACT.

Another case is given of failure due to low water. Some six months previous to this accident repairs had been made by putting in new radial stays, and had converted the longitudinal seams between crown and side sheets from riveted seams to welded seams. This had been done by cutting through the centre line of rivet holes and the sheets made flush. The sheets were then welded by the oxyacetylene proces, with the exception of five inches at each end. When the accident occurred these seams failed along the entire welded portion, the short riveted piece at each end remaining intact. The failure of these seams made the resulting explosion considerably more severe than would otherwise have been the case.

Another fatal accident involving the death of two people and the seriously injuring of three others, occurred through low water. The firebox in this case was a Wooten type, combustion chamber firebox, without a brick arch. The crown and side sheets were of one-piece construction ,the combustion chamber crown sheet seam being welded, and crown sheet supported by radial stays throughout. The initial rupture took place at the transverse welded seam, about 3 feet 2 inches back from the flue sheet. The crown sheet of the firebox was blown down, and carried with it part of both side sheets, which tore diagonally from each end of the transverse welded seam. The combustion chamber crown sheet remained intact, and the calking edge of the top flue sheet seam, was not sprung on either fire or water sides. This seam was two inches higher than the back end of the crown sheet.

Still another case was that of firebox boiler with crown and side sheets of firebox constructed of three pieces having riveted longitudinal crown and side sheet seams, without a transverse longitudinal welded seam. In this case the water line was ten inches below the highest point of the crown sheet. The intense heat that this sheet was subjected to may be gathered from the fact that rivet holes had stretched as much as 1⅛ inches in some cases. The sheet had pocketed between the stays to a depth of ¼ inch.

Electrical Energy Generating Stations—III

The Third of a Series of Articles Dealing With the Design of the Power Plant. This Article Discusses the Adaptability of the Three Different Classes of Prime Movers for Different Services

By TERRELL CROFT
[Copyright; all rights reserved by the author]

THE TYPE *of prime mover which should be adopted for any specific installation* is, in general, principally a question of economics. Usually, that prime mover is the best one for a certain installation which will produce the energy in that installation at the least cost per kilowatt-hour. There are many elements which must be considered in such a determination of least cost. Some of these will be described briefly in the articles which follow. Figs. 17 and 18 show respectively the horse-power outputs of the prime movers used in central stations and industrial plants in the United States.

The Application of Steam Prime Movers should, in the case of very small installations, be restricted to locations where coal is very cheap and where water power is not available. In medium-capacity installations, say those of from 300 to 5,000 kw., steam plants may be more economical than internal-combustion-engine plants or those hydro-electric plants which require considerable capital expenditure for development. In large plants, where units of capacities of 5,000 kw., and upward may be utilized effectively, modern steam turbo generator energy generation will ordinarily prove much more economical than generation with an internal combustion engine. It will also prove more economical than hydro-electric generation

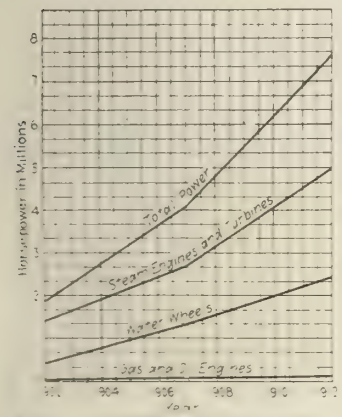

FIG. 17—PRIME MOVERS USED IN CENTRAL STATIONS. (From E. A. Lof, Coal Age, Feb. 6, 1915.)

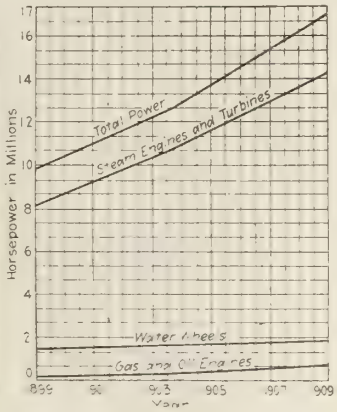

FIG. 18—PRIME MOVERS USED IN MANUFACTURING INDUSTRIES. (From E. A. Log, Coal Age, Feb. 6, 1919.)

and transmission unless the investment required to develop the hydro-electric properties is unusually small.

*NOTE**—"The progress of the steam turbine (Fig. 19) has been so great that it has practically displaced the gas engine. As the cost of the gas engine unit is probtically an unlimited supply of power. The steam turbine, the gas engine has been practically put out of the running insofar as large power plant work is concerned." "Another interesting side light in this matter is the value of the turbine as the general prime mover in competition with any thing else that could be cited. Fifteen years ago hydro-electric power developments were looked on as a choice investment worth lots of money with almost any cost of development. Water powers were developed that cost $200, $250 and $300. To-day you could not get money for an investment of that kind. The steam turbine has risen so high in efficiency and economy and decreased so much in first cost that it has driven out all possibility of developing many of these water powers. When you allow for the fixed charges, the steam turbine can make power more cheaply than the high-priced hydro-electric development." "Consider the case of Niagara Falls, where there are no dams required and where there is practicall an unlimited supply of power. The steam turbine plant can compete with Niagara power to-day, as long as the load factor of the Falls power is less than 50 per cent. The only chance for a financially successful water power development is on the basis of a high load factory."

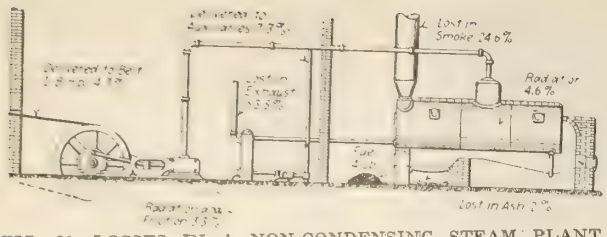

FIG. 21—LOSSES IN A NON-CONDENSING STEAM PLANT. (From "Producer Gas From Low-grade Fuels," Practical Engineer, Dec. 15, 1914, p. 1200.)

cost per kw. with the large turbo units is something like a fifth of the cost of equivalent reciprocating engine units. Furthermore, the water rates, that is, the steam consumptions of the large turbines, are in the neighborhood of one-half of the equivalent consumptions of reciprocating engine units.

Internal-Combustion-Engine Prime Movers are Effectively used at the present state of the art only in plants of small and medium capacity unless the cost of coal or of an hydro-electric development is unusually large. In small plants, say those up to 300 kw. in capacity, the internal-combustion-engine prime movers may, unless the

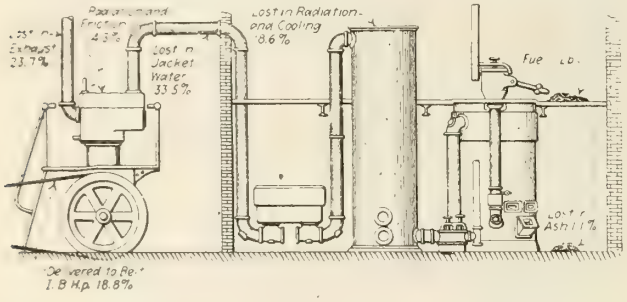

FIG. 22—LOSS IN A SUCTION GAS PRODUCER PLANT. (Practical Engineer, Dec. 15, 1914, p. 1200)

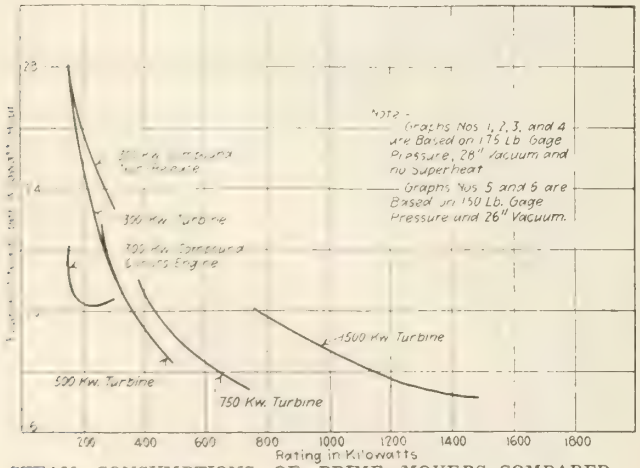
cost of coal is very low, be more economical than steam engine plants. This is particularly true of small plants which operate only a portion of the twenty-four hours. For a small central station plant which operates only at night or for a small industrial plant which operates only during the day, an oil or gas engine usually would generate power at minimum cost because such an engine does not involve the stand-by losses which obtain with the steam prime movers. As suggested in the above note, where a large power output is required, the internal combustion engine has been put entirely out of the running by the condensing steam turbine. If the cost of development is not excessive, it may be possible to generate power with a water-wheel—hydraulic turbine—cheaper than with an internal combustion engine. The producer gas plants, which are much more economical than ordinary non-condensing, medium-capacity steam-engine plant, (Fig 21 and 22) cannot usually compete with the condensing turbo-



STEAM CONSUMPTIONS OF PRIME MOVERS COMPARED.

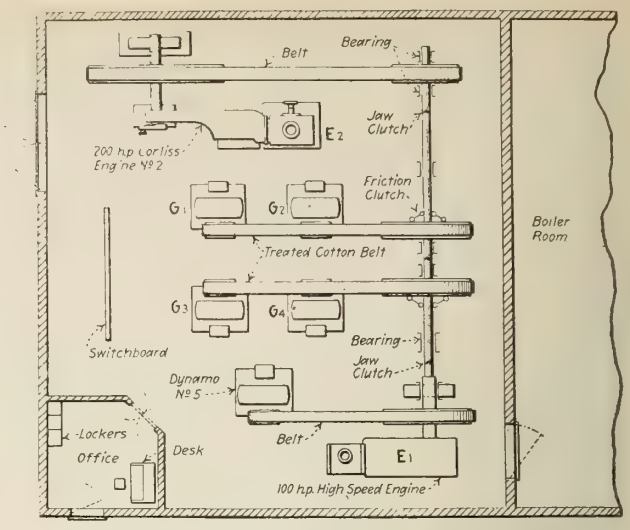


FIG. 24—LAYOUT FOR A SMALL BELTED PLANT DRIVEN BY A CORLISS AND HIGH SPEED ENGINE.

generator outfit unless the cost of fuel which may be used in the producer is very low.

Hydraulic Prime Movers are Most Economical where the cost of developing the hydro-electric plant is not excessive. It appears to be the common impression that merely because the water, which drives the turbines or water-wheel in a hydro-electric plant, costs nothing, that the cost of the power developed should be correspondingly low. This is far from the truth, because in determining the total cost of the power developed, it is necessary to include the fixed charges (interest, depreciation, insurance, taxes and the like) on the investment required to develop the hydro-electric property. If it is necessary to pay these fixed charges on an expensive dam and on a large real-estate investment required for the storage-water area, and then in addition pay the fixed charges on a long, expensive transmission line, such fixed charges may more than overbalance the cost of the coal and attendance that would be required by a modern steam station. The fixed charges on the transmission line should, usually, properly be in-

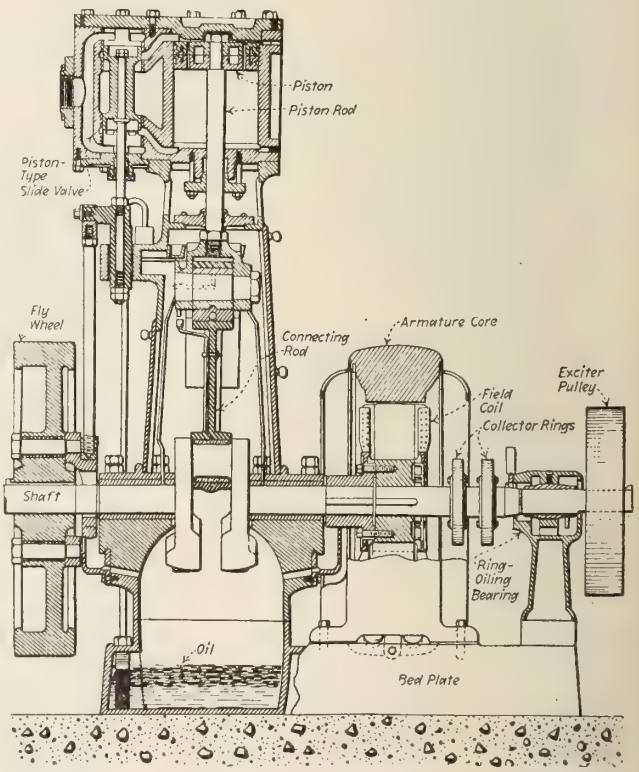

FIG. 25—DIRECT CONNECTED GENERATING UNIT. A HIGH-SPEED PISTON-VALVE ENGINE DRIVING A SMALL ALTERNATOR

cluded with those on the hydro-electric plant and development. Without the transmission line the plant would be useless.

The Development of Low-Head Hydro-Electric Plants is likely to involve excessive cost. On the other hand, if,

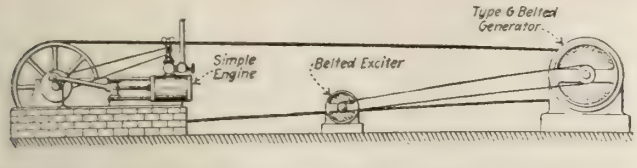

FIG. 26—A HIGH-SPEED SIMPLE ENGINE BELTED TO A SMALL THREE PHASE GENERATOR.

due to local conditions, it is possible to install a hydro-electric plant without incurring a large investment in dams, storage reservoirs and transmission lines, hydro-electric power may be developed very cheaply. Some of the high-head plants used in the West involve a relatively low first cost per kw. of capacity and, hence, can produce power very cheaply. Some hydro-electric plants for towns

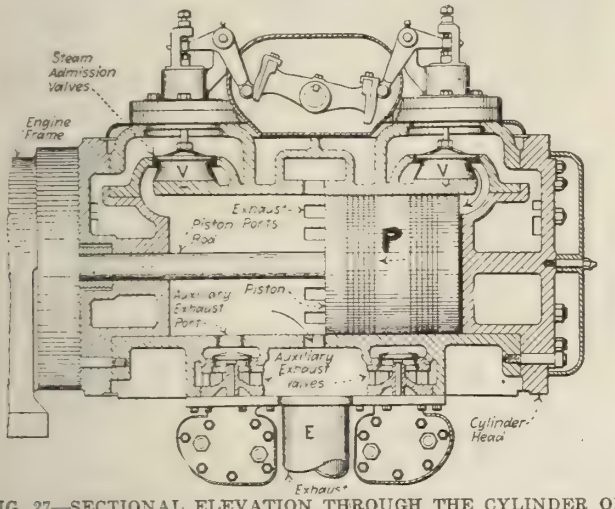

FIG. 27—SECTIONAL ELEVATION THROUGH THE CYLINDER OF A SKINNER-POPPET-VALVE UNIFLOW ENGINE. (FULL OPENING EXHAUST THROUGH CENTRAL PORTS.)

and factories are often economical where the plant can be located close to the load—so that a transmission line investment is not required—particularly if an expensive dam and storage reservoir is not necessary.

STEAM PRIME MOVER STATIONS.

Steam Plants May be Conveniently Divided Into Four Classes.* While there can be no definite dividing line, it is convenient to consider steam plants under four headings:— (1) *Small Plants,* to include all of those under 300 kw. capacity, (2) *Medium Plants,* to include those between 3,000 and 5,000 kw. capacity, (3) *Large Plants,* those between 5,000 and 50,000 kw. capacity, and (4) *Extra Large Plants,* which include those above 50,000 kw. capacity.

In Small Steam Plants it is usually considered good practice to install only one or two units. Often only one unit of suffcient capacity to carry the entire load is used. The graph of Fig. 23 indicates the water rates of some relatively-small steam prime movers. It will be noted that the efficiency at full load decreases rapidly as the size of

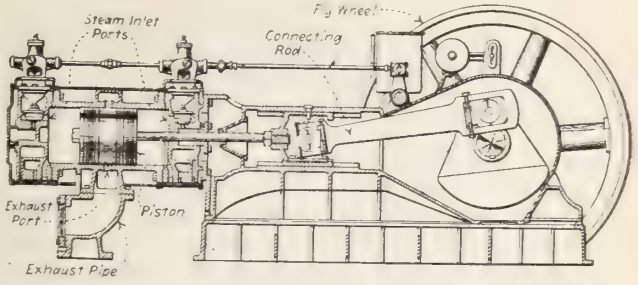

FIG. 29—SECTIONAL ELEVATION SHOWING CONSTRUCTION OF THE AMES-STUMPH UNIFLOW ENGINE.

the turbine decreases. It should also be noted that with all of the units, the efficiency decreases rapidly as the load on the unit decreases. Hence, it is desirable to use the largest units possible and to always operate them at as nearly full load as is feasible. Frequently it is desirable, in these small plants, to operate non-condensing because the fixed and operating charges on the condensing equipment may be such that its first cost is not justified. In such installations where simplicity and reliability of service are the most important factors, a high-speed engine of the slide valve or non-releasing Corliss-valve type may be used. Or instead, Corliss engines may be installed.

FIG. 30—CHARACTERISTIC PERFORMANCE GRAPHS OF THE UNIFLOW ENGINE. (From Characteristics of Uniflow-Generating Units, Electrical World, Feb. 10, 1917, p. 260.)

Non-condensing reciprocating steam engines are more economical than non-condensing turbines.

In Considering Belted vs. Direct-Connected Steam Engine Units for Small Plants, it should be recognized that the cost of the belted outfit is always lower than that of the direct-connected, because where the generator is belted it may operate at high speed—which involves low generator cost. If the generator is direct-connected to the engine, its speed must be the same as that of the engine, which is relatively low. Fig. 24 shows a typical belted in-

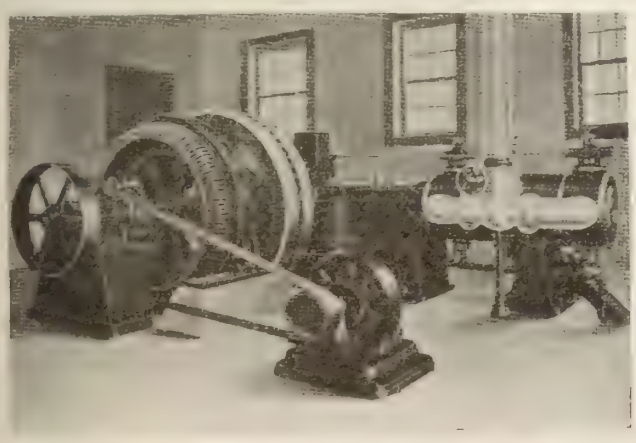

Fig. 28—An 18 in. x 24 in., 200 R.P.M. Ames-Stumph Uniflow Engine operating condensing at 141-lb. pressure, superheat approx. 100 deg., driving an Allis-Chalmers 2500-kv.-a 220 volt, 3 phase, 60 cycle generator, served by a 125 volt exciter. Installed in plant of the Winsor, Vt., Electric Light Company.

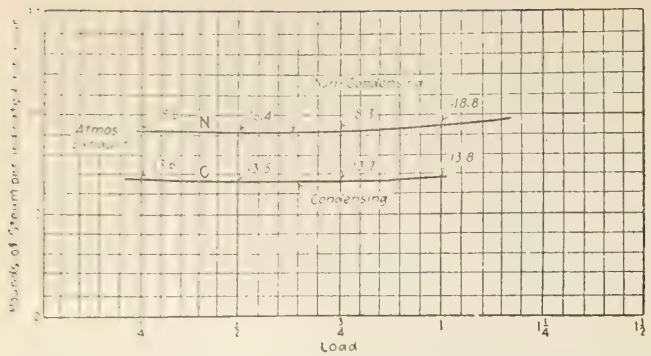

Fig. 31—Graphs showing water rates of a Skinner 21 in. by 22 in. Uniflow engine running non-condensing and condensing, saturated steam at 140 lbs. This and the next illustration are from data on engines which were direct-connected to generator of 200 true kw. capacity and would be considered 320 h.p. engines at normal full load. However, the engines are good for 400 indicated horsepower for maximum continuous operation.

stallation*. A high speed engine, *E*1, is direct-connected to the jack shaft from which the generators are belted. A Corliss engine is also belted to the jack shaft. Both of the engines are used to pull the station at time of peak load. At other times either the Corliss engine, *E*2, or the high-speed engine, *E*1, were used to pull the load, depending upon which could operate most economically. Small stations of this general character may give satisfactory service in towns where the cost of coal is low and

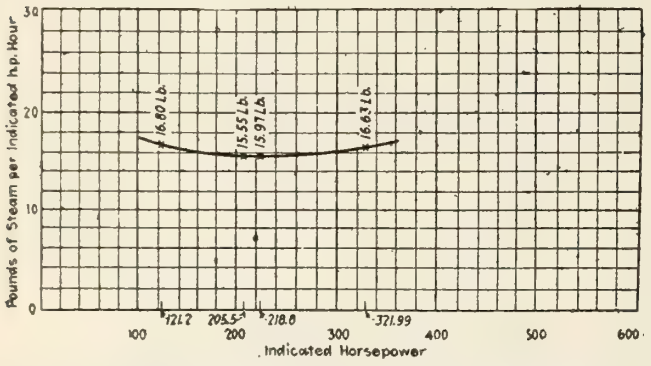

FIG. 32—GRAPH SHOWING WATER RATE OF A 21 IN. BY 22 IN. SKINNER UNIFLOW ENGINE OPERATING AT A PRESSURE OF 149.1 IBS. AND WITH A SUPERHEAT OF 102.5 DEG. FAH.

where reliability and ease of operation are of more importance than high economy.

A Small Direct-Connected Generating Unit, similar to that of Fig. 25, may be used where economy of space is an important factor. A unit of this type which is equipped with a small slide valve engine will not be as economical as one having an engine with an automatic cut-off valve gear.

A Small Alternating-Current Generator Belted to a High-Speed Slide Calve Engine is shown in Fig. 26. Units

*F. W. Salmon, "Practical Engineer," June 15, 1915

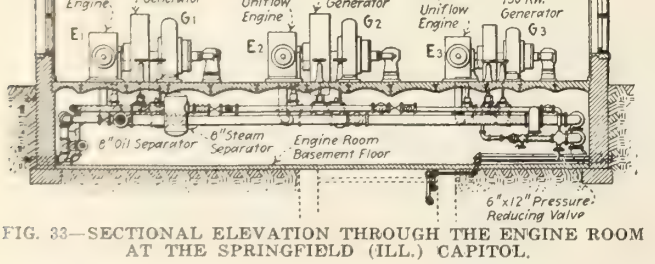

FIG. 33—SECTIONAL ELEVATION THROUGH THE ENGINE ROOM AT THE SPRINGFIELD (ILL.) CAPITOL.

of this character may be used in small stations where the cost of fuel is low and where an easily-handled outfit of very low first cost is imperative.

Uniflow Engines, which have been used in Europe for a considerable period, but which have only recently been thoroughly developed in the United States, afford economical prime movers for small units. A uniflow engine is one in which the steam (Fig. 27) leaves the cylinder at its middle point, *E*. The steam enters the cylinder through valves, V, at either end and is discharged through ports in the middle which are opened and closed by the cylinder piston, *P*, which acts as an exhaust valve. The economical performance of the uniflow engine is due to the fact that cylinder heads are always maintained at the same temperature so that there is little condensation in the cylinder. The steam alawys flows in one direction. With the simple

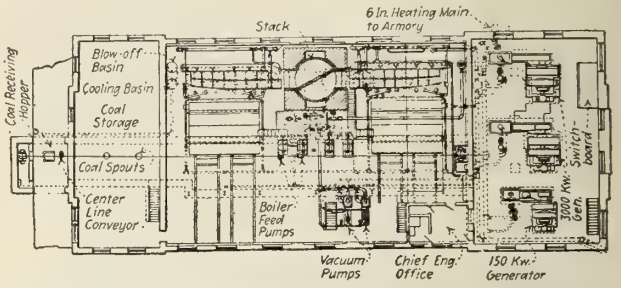

FIG. 34—PLAN OF THE UNIFLOW ENGINE PLANT AND THE BOILER PLANT IN THE SPRINGFIELD (ILL.) CAPITOL.

engine, each cylinder head alternately is heated and cooled as the steam is permitted to enter and exhaust from the cylinder. Uniflow engines can be used with superheated steam, which results in further economics. It appears that modern uniflow engines in capacities up to about 500 horsepower are as economical as any of the other types of steam prime movers. They can be obtained for both condensing or non-condensing service, or for combined condensing and non-condensing operation. Fig. 28 shows a uniflow engine direct-connected to an alternating-current generator which is served by a belted exciter. Fig. 29 shows the construction of an engine of the type reproduced in Fig. 28. Tests of uniflow engines operating non-condensing at 140 lb. boiler pressure have shown an economy of 30 lb. of steam per kwh. when operating at full load. Fig. 30 gives typical economy graphs for a uniflow unit as compared with a turbo-generator. It will be noted

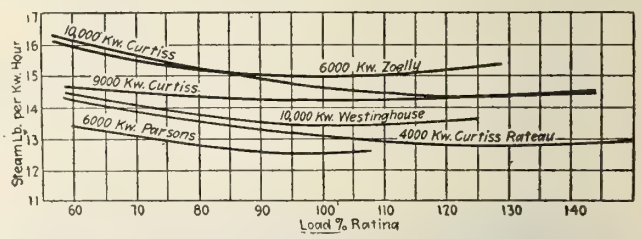

FIG. 35—WATER RATE GRAPHS OF SOME MEDIUM-CAPACITY CONDENSING TURBINES. (Standard Handbook.)

that the performance graph of the uniflow engine near the no-load point is almost horizontal. That is its efficiency does not change greatly with change in load, around the full-load point. This feature is shown in the performance graphs of Figs. 31 and 32.

A Uniflow Engine Installation is shown in Figs. 33 and 34. These illustrate the equipment used for supplying electrical energy to the State buildings at Springfield, Illinois. Three direct-connected engine-driven units are installed. Each unit comprises a Chuse-Poppet valve engine direct-connected to a Westinghouse direct-current generator. One 18 x 21 in. engine drives a 200-r.p.m., 150 kw., 125-volt generator Each of the other units is driven by a 22 x 28 in. engine, the generators being rated at 300 kw., and operated at 150 r.p.m. The 150-kw. unit is operated when the load is light—on Sundays and at

night. The present day-load is handled by one of the 300-kw. units.

Steam Turbine Stations have recently attained a position of great importance. This is particularly true of the stations wherein units of 20,000 kva. and greater capacities may be utilized. As suggested above, a modern, large, steam-turbine generates power, under ordinary conditions, more economically than can a prime mover of any of the other types. Steam turbines are now widely used even in capacities of under 500 kw. They are also because of their simplicity and reliability, used for driving the auxiliary apparatus in a station, such as condenser pumps and feed pumps. High steam pressures are desirable, hence pressures ranging from 150 to 250 lb. are encountered. Since superheating also increases the economy, the steam is usually superheated from 125 to 150 deg. High vacuums ranging from 28 to 29 in. are employed.

*Example** —A 500-kw. turbo unit, when operating on steam pressure of 150lbs. and 125 deg. of superheat and a 28-in. vacuum, has a steam consumption of approximately 17½ lb. per kwh. A 15,000-kw. unit operating at a steam pressure of 250 lb. with 125 deg. of superheat and a 29-in. vacuum, has a steam consumption of only 11½ lb. per kwh.

Why the Large Steam Turbine is so Economical may be explained thus: *First*, since no lubrication is necessary in the parts of the turbine with which the steam comes in contact, a higher degree of superheat is possible with it than with the reciprocating engine, for which cylinder lubrication is necessary. *Second*, when the turbine is used condensing, as it must be for maximum economy, the turbine utilizes the expansive power of the steam down to the highest vacuum which can be developed. The reciprocating engine can utilize the expansive power of the steam only down to possibly a 25 or 26-in. vacuum. If an endeavor is made with a reciprocating engine to expand the pressure of a high vacuum, the low-pressure cylinders and the reciprocating parts associated therewith would be so large that their cost and frictional losses would more than offset the theoretical economics resulting therefrom. It is evident, therefore, from the foregoing, that a much greater part of the total energy is the system can be realized with the turbine than with the reciprocating engine. Another factor which renders the turbine so economical, is its low first cost per unit of power output. This is because the turbine is inherently a high speed prime mover.

The Efficiency Graph of the Turbine is almost flat, Fig. 35. It follows that a turbine operates at good economy over a wide range of loads.

The Growth in the Capacities of Turbo-Generator Units has been almost phenomenal. As suggested in the graph of Fig. 36, single units have been manufactured having outputs of 60,000 kw. The manufacturers assert that there is no reason why units of greater capacities than 60,000 kw. cannot be built provided there is a demand for them. Fig. 36 indicates the gradual increase in the capacities of the generating units in the stations of one central station company.

A Comparison of the Steam Turbine and the Steam Engine as regards their applications is summarized in the following data* which relates particularly to units of less than 500 horsepower.

*NOTE**—*Applicability of Turbines.* (1) direct-connected units, operating condensing. 60-cycle generators in all sizes, also 25-cycle generators above 1,000 kw. capacity. Direct-current generators in sizes up to 1,000 kw. capacity. Direct-current generators in sizes up to 1,000 kw. capacity including exciter units of all sizes. Centrifugal pumping machinery operating under substantially-constant-head-and-quantity conditions and moderately high head, say from 100 feet up, depending upon the size of the unit.

Fans and blowers for delivering air at pressures from 1½ in. water column to 30 lb. per square in.

(2) Direct-connected units, operating non-condensing for all the above purposes, in those cases wherein steam economy is not the prime factor or where the exhaust steam can be completely utilized, and, in the latter case, particularly where oil-free exhaust steam is desirable or essential.

(3) Geared units, operating straight condensing or non-condensing for all the above mentioned applications, and in addition many others which would otherwise fall in the category of the steam engine, on account of the relatively-slow speed of the apparatus to be driven.

*J. S. Barstow, "Turbines vs. Engines in Units of Small Capacities," a paper read before the A.S.M.E.

Slag Wool For Covering Steam Pipes

The results of some tests on the efficiency of slag wool as a covering for steam pipes, carried out at the National Physical Laboratory, are forwarded by Messrs. Frederick Jones and Co., of Kentish Town. The test pipe used was a piece of 4-in. steel steam pipe, 13-ft. 8¼-in. long between flanges, and experiments were made with two thicknesses of covering (nominally 1-in. and 2-in), at three different steam pressures. With the thinner covering the saving of heat, as compared with the loss from a similar bare pipe, was 84.9 per cent., with a steam pressure (gauge) of 53.9-lb. per sq. in., 84.9 per cent. with a pressure of 109.2-lb., and 85.5 per cent. with a pressure of 256.3-lb. The results for the thicker covering was 91.8 per cent. with a pressure of 54.1-lb., per sq. in., 91.6 per cent. with 107.8-lb. and 92.5 per cent. with 258.9-lb. The principle on which the tests were based was that of measuring the weight of steam condensed in the pipes during one hour, two such one-hour runs constituting a test. There was no flow of steam through the pipes, except a very small amount due to the condensation; hence, in practice, where there is flow, the quantity of heat lost for the same difference of temperature between steam and air would not be the same as in the test pipe, but the efficiency figure will not be materially affected thereby, since it is the ratio of two tests under nearly identical conditions.

Storm Warning For Electric Plant

An article in the Scientific American Monthly—the new form in which the Scientific American Supplement is being published—gives an interesting description of the arrangements used in the Waterside power house, New York, to warn the staff of impending thunderstorms, which may have the effect of greatly increasing the load on the alpnt. Atennæ are mounted on the roof of the station and connected to an alarm. At a time varying from two to seven hours, depending upon whether the path of the storm is direct or roundabout, the bell may begin to ring, at intervals of from five to fifteen minutes, giving a warning of some distant atmospheric disturbance, indicating a storm possibly 100 miles away. This is regarded merely as a preliminary warning, for as the storm approaches the bell will ring more frequently. When about two hours away, the bell will ring about once every half-minute or minute; and when this occurs the reserve boilers are ordered into service and the auxiliaries of extra generating units are started and the generating units themselves may be run at low speed. The bell rings continuously about one-half or one hour before the storm reaches the city, and even at this time the sky may be unclouded to the eye, even of an experienced storm observer.

Erecting Boiler and Engine Foundations

One of a Series of Articles Descriptive of the Proper Methods of Design and Construction for Foundations of Various Types of Power Plant Apparatus

BY T. H. FENNER

ONE of the most important things for an erecting engineer, as mentioned at the conclusion of the last article, is to visualize the progress of events. To handle heavy and awkward masses, with the minimum of effort, and the maximum of safety, requires confidence in one's own ability, the capacity to exact instant obedience from the men on the job, and a cool head. Furthermore, never for the sake of saving a few minutes, take a chance on doubtful material. A rope or chain that you are not sure of, a plank that is on the light side, a piece of blocking improperly placed, can all bring disaster. Every man who has had experience in this kind of work can give you instances where taking a chance has delayed the job and injured men. Don't do it. Be sure everything is right, and then go ahead in confidence.

Let us suppose that the boiler is standing on a flat car, on a siding some little distance from the boiler room. It will very likely be on skids, and some of the mountings, such as safety and stop valves, may be in place. If there are no mountings on it, there will at least be the suspension brackets, which usually preclude any idea of rolling, which would be the simplest method. In handling a boiler of the H. R. T. type, do not forget that it is very easy, by carelessness, to flatten in a plate. A boiler dropped a short distance even, and landing on a narrow block, stands a good chance of having a plate dinged in. This applies more particularly to the boilers having plates of ⅜ in. and under. Therefore don't get the idea because the boiler is made of steel that it can be knocked round any old way. To get the boiler off the car, first make sure that the brackets are on good and fast, and the wheels well blocked. Build an inclined plane of timbers from the deck of the car to the ground, and make it long enough to ease the boiler down in handy fashion. The supports for this runaway at the car itself can be well made by a couple of good strong barrels, and at a short distance back start the blocking as additional support Now what size timbers will be needed to carry the weight of the boiler? Say the boiler and skids as they stand on the car weigh 20,000 lbs. If the timbers we are to run the boiler down are supported every ten feet, what size will they have to be to support the boiler?

Now in this matter of selecting timbers and blocking the average man is ruled by instinct, usually erring well on the side of excessive strength. This of course is good, but it sometimes happens the error is made the other way. Again useless labor is involved in lugging heavy beams around when smaller ones would do. The factors governing the size of the timbers are the breaking strength of the material, and the distance between supports. Now to handle a proposition like a boiler, you require a good broad surface for the skids to travel on at least as wide as the skids themselves. That is the factor governing the width. The depth will be the same, as square timber is usually the handiest. However, do not forget that the strength of a beam varies with the square of the depth. That is a beam 10×10 will have a breaking strength of $\frac{S \times 10^3}{6}$, while one of 10×12, with the long side vertical will have a strength of $\frac{S \times 10 \times 12^2}{6}$. In the first case the result is $\frac{1{,}000\ S}{6}$, while in the second it will be $\frac{1{,}440\ S}{6}$, a very respectable difference.

Suppose there are some 8-inch square timbers handy. The safe strength of timbers under a deflecting stress may be taken as 1,000 lbs. per square inch, giving a factor of safety as 9. Therefore an 8-inch square beam will have a safe strength of

$$\frac{1{,}000 \times 8^3}{6} = 85{,}333, \text{ say } 85{,}000 \text{ lbs.}$$

The weight of the boiler is 20,000 lbs., and this will be divided between two beams, 10,000 lbs. on each. What distance should the supporting blocks be spaced, or can they be spaced? Consider the load as a uniformly distributed load on a beam supported at each end. Then the bending moment, or the force tending to produce a deflection of the beams at the centre will be $\frac{W\ l}{8}$, that is W = weight, l = length in inches between supports.

When $\frac{W\ l}{8} = 85{,}333$ or $\frac{10{,}000 \times l}{8} = 85{,}333$, therefore $l = \frac{85{,}333 \times 8}{10{,}000} = 68.2664$, say 68 inches.

However the length of the skids is 20 feet so that the actual weight coming on the beams between supports at this distance would be much less than 10,000. We can safely place the supports 10 feet apart, because even then the weight would always be divided between at least three sections of the beam. The crushing strength of wood is about 8,000 lbs. per square inch, and allowing a factor of safety of 4 would be 2,000 lbs. Therefore any good square blocking, solidly placed, and wide enough to give a good landing for the beams will be suitable.

If the ground is soft, get some good wide planks and lay them down at the end of the runway to prevent the skids sinking into the earth. With hard ground this is unnecessary. Get several lengths of 2-inch iron pipe long enough to extend over the width of the runway and get two good pairs of chain blocks to check the boiler back as it goes down the beams. These must be secured to the body of the car, and the slings hooked up to the brackets on each side of the boiler. In this way they can be used for straightening up if the boiler tends to slide off to one side or the other. The strength of a rope ¾ inch diameter is roughly 2 tons. A good rough rule for the breaking strength of rope is circumference $^2 \times 720$. This applied to a ½ in. diam. rope would give $(.5 \times 3.1416)^2 \times 720 = 1{,}800$ roughly. This of course is the breaking strength and a factor of safety of 4 or 5 should be used, according to the condition of the rope. In fact, a higher factor than that can do no harm. In using blocks and tackle, be sure they are good enough for the job, and see every sling is made fast properly yourself. If there is a man on the job who knows more of handling tackle than you do yourself, let him run it and observe his methods. A faulty sling, a knot that slips, may mean valuable machinery damaged and loss of life or limb. Be sure.

Having rigged your runway, and got the checking tackle, or preventer guys, whichever you like to call them, made fast, the next step is to get the skid pried up at one end high enough to get a roller under. This may be done with bars, but on a heavy piece like a boiler, it will probably be necessary to use a jack. Lift the end of the skid nearest the runway high enough to run your pipe roller back to the centre of the boiler, and then stick another one in near the front end. Have a third ready to put in as the boiler moves along. You will need half a dozen at least. Once you have got the weight of the boiler on the rollers, it will be easy for three or four men with bars to move it forward. There is another point to watch. As the end of the boiler comes clear of the car floor, it will overhang the runway, but owing to the greater part of the weight being on the car will not land. It will have to come off the car far enough for the forward end to overbalance before it will tilt downwards on to the running beams. It is

at this point that you need to be careful. Take two pieces of iron pipe that will enter the tubes and put them in the two outside tubes (right and left) of the bottom row. Take two pairs of blocks, easy running rope blocks if you like, and make them fast to the car near the front end, making the other ends fast to a sling round each of the pieces of pipe. Heave short on these, and you can effectually prevent any sudden tendency to twist on the part of the boiler, and ease the descent of the overhanging end. Once you have got the skids on the runway with the rollers under them, it is only a question of easing away on your blocks till the boiler rests on terra firma. From there into the boiler house is a question of rollers and pinch bars, assisted by block and tackle wherever a purchase can be secured.

The boiler having been manoeuvred into position, and the steel work for suspending it being already erected, the lifting may be done by chain blocks or jacks. If chain blocks are available, they form the handiest method. A block is slung at each corner of the suspension girders, corresponding with the brackets. The blocks should be of 3 tons capacity each, and as the boiler is hoisted, it should be blocked up from underneath, so that the failure of any part of the lifting apparatus would not be attended by any harm. If jacks are used, four should be employed. The preliminary lifting may be done by blocking up under the brackets, and raising one end at a time till head room for the jacks can be secured underneath the skids. A jack at each corner makes the lifting easily controlled. When the boiler is high enough, insert the suspension bolts, and the job is complete. The brickwork can then be put in. In the next article something will be said about settings.

HAND FIRING SOFT COAL

IN ORDER to secure efficient combustion in any boiler furnace, the furnace must be correctly designed and properly operated. A furnace designed according to correct principles is ineffective without proper operation, and no fireman can secure the best results with a furnace unsuited to the kind and quantity of fuel burned.

In this bulletin, which is intended for the use of those in charge of hand-fired plants; mention only is made of some of the requirements of furnaces for burning soft coal, it being the purpose to explain those firing methods which practical experience has shown to be the most sucessful under average conditions in this state. While the particular methods of firing explained will not make it possible to obtain equal success in the operation of all furnaces or in the burning of all kinds of fuel, their adoption will give satisfactory results in most cases.

Cleaning Fires

On account of the fact that clinker and coarse ash will not pass through the grates, it is necessary to clean the fires from time to time.

In the side method of cleaning fires, one side of the fire is cleaned at a time. The good coal is moved to one side of the grate, with the hoe or slice bar and the exposed clinker and ash removed. After one side of the grate has been cleaned, the good coal is all moved to that side and the rest of the grate cleaned. The burning fuel is then spread over the entire grate.

In the front to rear method of cleaning the burning coal is pushed back to the bridge wall and the coarse ash and clinker removed, after which the coal is spread over the grate.

In many plants, especially small ones, the fireman has other duties, in addition to firing, so that large charges must be fired at rather long intervals. When such is the case, the coking method of firing should be used.

In the coking method, the fresh coal is fired at the front of the grate, after most of the live coal has been pushed back. A considerable area of live coal is left uncovered at the back of the furnace, so that the volatile matter from the fresh charge is burned in passing over this hot coal. The fire door should be cracked to admit the air required for combustion of the volatile matter. When the coal is coked it should be spread evenly over the entire fuel bed, and the fire door and fire door damper closed. Care should be used in spreading, not to stir up the fire.

Smoke Prevention

Smoke is caused by the presence of very fine particles of unburned carbon in the gases which pass out of the fire box. These particles are so fine that they are carried along by the slightest current and are able to float in the air for some time, finally being deposited as soot.

Practically all smoke is produced during the time that distillation is taking place, that is after firing fresh fuel. The products of perfect combustion being invisible gases, smoke appears only when combustion is incomplete, due to lack of air, imperfect mixing of air and gases, or cooling of the mixture before combustion takes place. Under these conditions, some of the carbon in the volatile matter is unconsumed and passes out as smoke.

It is often stated that black smoke issuing from a chimney for any considerable length of time is an indication that the full heating value of the fuel is not being utilized on account of furnaces improperly designed for the kind and quality of fuel being burned, or improper methods of firing or both. While this statement is absolutely true, the fact that a chimney is not smoking must not be taken as an indication of high furnace efficiency. As a matter of fact, this smokeless condition may be due to the dilution of the smoke by the admission of large quantities of excess air to the furnace. Every pound of air admitted to the furnace in excess of the amount actually required for combustion, simply decreases the efficiency of the furnace by absorbing heat and carrying it up the stack. Smoke prevention or rather dilution by this means is expensive.

The matter of furnace design is very important in burning coal having a large percentage of volatile matter. The combustion chamber must be designed to provide for the thorough mixing of air with the gases before they pass out of the chamber. In order to maintain a high temperature, the gases must not be allowed to come into contact with the comparatively cool boiler shell or tubes until combustion is complete, otherwise they may be cooled below the ignition temperature and pass out unburned.

These requirements are usually taken care of by having a combustion chamber of considerable length provided with a suitable fire brick arch or by covering part of the cooling surfaces (tubes and shell) with fire clay blocks. Many of the arches used serve two purposes—in helping to mix the gases and keeping them from being cooled.

The most common fault in the design of hand fired furnaces using Iowa coal is that the combustion chamber is too small. This is probably due in large measure to the installation of equipment designed for burning eastern coals, many of which are low in volatile matter, while Iowa coals often contain above 40 per cent. volatile matter.

MUST WEAR PANTS

'El Universal', the leading newspaper of the City of Mexico, has this remarkable dispatch:

Morelia, Mex., April 21.—The Mayor, Senor Idalecio Contreras, has just issued a public order by which he makes obligatory the wearing of pants by the male residents and visitors when passing through the streets of the town. The order directs that all persons who do not possess these articles of wearing apparel must provide themselves with these not later than May 5. Failure to comply with the order is punishable, and the offender must secure pants before released from custody. The Mayor specifies that the use of underwear will not be regarded as complying with the order.

AUTOGENOUS WELDING

Continued from page 136

From the above examples and the rules set forth by the Steam Boiler and Fly Wheel Service Bureau, the limits of usefulness of the autogenous welding process are clearly defined. It is evident that for building up corroded portions of plates, or ensuring a water tight joint, this method can well be used. In places where the full stress on the metal is liable to come upon the weld, without other support, it should not be employed. Even in such work as piecing tubes together it is not allowed, whereas one would have thought this was a legitimate field for the process.

It must be remembered that these rules have been drawn up from the experience of engineers, all of whom have had a wide field of observation. Power plant engineers and owners should read these rules carefully and keep them for reference.

The St. Lawrence River

THE deepening of the St. Lawrence and its improvements for navigational purposes together with the vast amount of potential power waiting for development, render the work of investigation now being undertaken by the Joint International Commission of very great interest to both Canada and the United States.

It is evident that powerful interests are opposed to any development of this character, but it is evident that their opposition arises from selfish motives. The railroads, as might be expected, are putting forth strong efforts to have the project defeated, and it is interesting to note that some of the Eastern States, and cities along the Atlantic seaboard of the United States, have joined with them in opposition. It is true that were ocean-going ships able to reach the head of the Great Lakes, the immense grain trade from the West would be diverted, and thus lost to the railroads. This, after all, should cause them little worry since at the present time they are unable to handle it in anything like a satisfactory manner.

In shipping by an all-water route to Europe the saving on each bushel of grain would be no small item. And similar economies would be apparent in other ways.

When the power possibilities are investigated the magnitude of the river flow and its characteristics render a tremendous amount of power available. The mean annual flow at the head of the river is in the neighborhood of 241,000 second-feet, and owing to the effect of the Great Lakes which act as storage reservoirs, the flow is remarkably low. The maximum and minimum flows differ by only about 25 per cent.

Alexander T. V. Vogelsang, the First Assistant Secretary of the Interior, Washington, is the authority for the statement that the amount of theoretical power per foot of fall in the St. Lawrence River, as shown by the mean annual flow is 27,360 horse power, and as a total fall of 92 feet is available in the international section of the river, the theoretical power in that section is about 2,520,000 horse power. Assuming that only 70 per cent. of this energy can be made available on account of losses in head and influences of water wheels and generating equipment, this stretch of the river owned equally by the United States and Canada would furnish 1,764,000 horse power, or 882,000 horse power to each.

"About 95,000 horsepower of the portion belonging to the United States has already been developed by the St. Lawrence River Power Company by means of a canal which diverts a maximum of 30,000 second-feet from the river near the head of the Long Sault Rapids through the power house into Grass River which joins the St. Lawrence below the Long Sault Rapids. Here a head of about 40 feet is developed. After the power utilized at this development is deducted from the power of the portion belonging to the United States the power not yet developed in that portion of the river amounts to about 790,000 horsepower.

"As a horsepower is practically three-fourths of a kilowatt, 790,000 horsepower is equivalent to about 590,000 kilowatts. This amount of power is about one-third the total installed generating capacity of all the plants engaged in producing electricity for public use in the State of New York.

"If the development were so made that a certain amount of regulation of stream flow by storage in Lake Ontario were possible and if load conditions were adapted to the full utilization of all the power produced, it would appear that the share of the United States of the St. Lawrence River would be about 425,000,000 kilowatt-hours per month.

"The power possibilities of the St. Lawrence have therefore very large economic importance, and any plans for developing the river for navigation should make provision for the energy that it will afford. This provision can be made only by working out a comprehensive plan in which both Canada and the United States seek the best engineering and economic solution of the problem. No doubt private capital is available to make all this improvement in consideration of a grant of the power privilege, but," according to Mr. Vogelsang, "there is equally no doubt that this will not be done. Canada as well as the United States would not permit it."

Ask Yourself—

Am I hitched up right, or am I a round peg in a square hole?

Do I feel every drop of blood and every fibre in me tugging away at my ambition, saying "Amen" to my work?

Am I backing up my chance in life in every possible way, or am I sliding along the lines of least resistance?

Am I keeping myself fit to do the biggest thing possible to me every day of my life?

Am I working along the line of my talent, or am I getting my living by my weakness instead of my strength?

Am I strengthening my weak points, making my strong points stronger, and eliminating the things which are keeping me back, the enemies of my success?

Do I decide things quickly, finally, or am I forever on the fence, fearing to make definite decisions which I cannot reconsider?

Have I the initiative which begins things without being told to; which does things without waiting for others' instructions?

Do I dare to attempt the thing I instinctively feel capable of doing, and I know that I ought to do?

Have I the courage which dares to branch out in an original way, dares to make mistakes that may humiliate me if I should not happen to succeed?

Do I try to develop that bigger man back of the smaller man I am, by obeying the God-urge that ever bids me up and on to greater endeavor?

If you can answer the above questions in the right way, you will bring out a hundred per cent. of your ability instead of the fifty per cent. that the majority of young men are content to develop; you will attain your ambition and be what you long to be.—"Success."

Some Cane in Queensland

Queensland is an important producer of sugar cane, and in view of the world-wide search of natural vegetable sources for alcohol, the discovery of the utility of sugar cane in that direction is an important one for producers in Queensland. The official Journal of the Commonwealth Institute of Science and Industry says:—"The sugar content of cane varies very much, equally in the stems as in the tops. The amount will also depend on where the tops are cut off, whether they are to be left on the field to be ploughed in or taken to feed stock. If the threshing has been done some time before cutting, the green cane under the leaves ripens, and the cut is made just above the base of the last leaf. The percentage of hydrolisable sugars might be taken as 2.6 per cent. If a little more of the stalk is taken when cutting off the top, *i.e.*, below the last leaf, the percentage might rise to 4.6 per cent., or 5.9 per cent. as a maximum. The moisture would be about 70 per cent. One ton of cane tops should produce from 3.63 to 8.24 gallons of absolute alcohol, but varying up to, say, 7 gallons, depending on place of cutting off tops, ripeness of top, and variety of cane, etc. It is not very safe to generalize too much for calculation, and it is better to be on the conservative side and calculate on a rate of 4 to 5 gallons."

Conserve Your Boiler Tubes

THE power plant operator has little call to follow market conditions closely, and it comes as a shock to him occasionally that certain lines of supplies and repair part are almost unprocurable. Particularly is this true of boiler tubes and like products of the steel industry. This is no new thing, tubes have been scarce for some time, but a fairly good indication of the market at present for such material as seamless tubing, is furnished by the fact that several of the warehouses in Toronto are not able to correct the price list that is published elsewhere. It may be gauged from the other list that goes with it, viz., lap-welded. One firm volunteered the information that a 2-inch tube was worth 32 cents per foot at the present time. There is need for tubes, many of the cases calling for them being bona fide repair jobs that are badly needed.

Power From Peat

The high cost of fuel again raised the question of utilizing to a greater extent the large deposits of peat in Ireland, and it will be recalled that a report was issued some twelve months ago by the special committee appointed to inquire into the peat resources of that country. Meanwhile, successful results have been obtained by utilizing peat in gas producer plants, and at one works in Ireland it was stated that the quantity of peat consumed was equivalent to 2.78-lb. per i.h.p. hour, or, assuming 88 per cent. mechanical efficiency, 3.16-lb. per b.h.p. hour. Allowing 3-cwt. for banking, the all-round consumption was estimated as 3.5-lb. per b.h.p. hour, as an outside figure.

The peat used contained on the average about 25 per cent. of moisture, and it was calculated that by handling large quantities, and employing every practical labor-saving device, the peat could be won from the bog, dried, and be delivered for a radius of five miles into a generating station at a price which would not exceed 0.56 cents per unit of electricity generated. As against this it was stated that a modern steam turbine plant, operating at 160-lb. to 180-lb. pressure, 100 deg. F. superheat, and 28-in. vacuum would, under similar conditions of load, cost 0.84 cents per unit, with coal at $8.75 per ton, and that an anthracite gas plant would cost 0.72 cents per unit with anthracite at $11.25 per ton.— Engineering Supplement London Times, Jan. 20.

Still the World Goes On!

Progress in New Equipment

NEW RADIAL TYPE LOADER FOR RAPID AND ECONOMICAL LOADING OF LOOSE MATERIALS

In recent years the increasing use of sand, gravel, crushed stone, ashes, slag, etc., for road building, concrete work, and other purposes, as well as the increased storage of coal and coke, has caused the handling and re-handling of immense quantities of loose materials.

During the time that help was plentiful and cheap, the prevailing method was to use a gang of laborers to shovel materials from ground storage to wagons or trucks. However, the constantly increasing cost and acute shortage of labor demanded the substitution of mechanical handling machinery to replace the old expensive and laborious "hand shovel" method.

To meet this demand the Jeffrey Self-Propelling Loader was brought out about ten years ago, after extensive experiments and tests and careful study of the then existing conditions, being the first machine of its kind to be placed on the market, and has proved a remarkable labor saver and quick handler of materials.

It has been used with great success by hundreds of leading concerns, but in order to meet developments in the various industries and the constantly changing conditions, the Jeffrey Company has developed an improved design known as the Radial Loader, which overcomes all the objections of the old type of machine, and is the last word in design and construction.

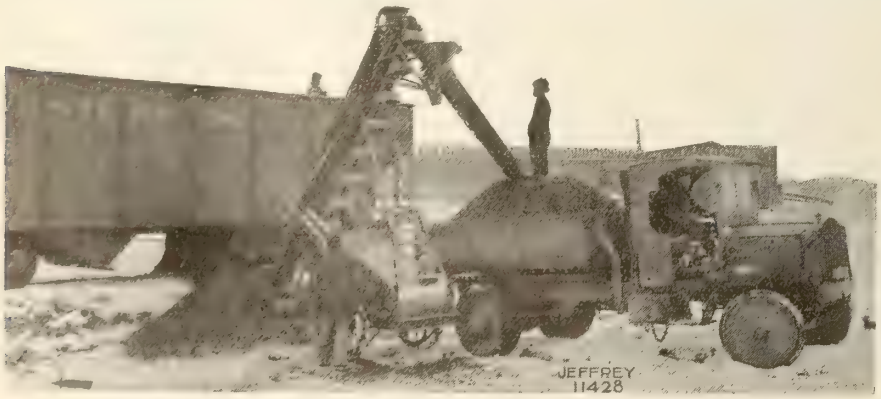
There is a great advantage in having the loader feed itself into the pile over other methods of hand shoveling or using a special mechanical device to pull the materials in front of the buckets. The greatest objection to the old 4-wheel type of Self-Propelling Loader was its inability to feed into the pile.

SHOWING THE EXTREMELY SHORT TURNING RADIUS.

The three-wheel construction of the Jeffrey Radial Loader enables it to move backward and forward along straight lines into a pile of material, or to cut wide swaths across the face of a pile by swinging alternately upon its driving wheels as pivots, which action is obtained through the use in its driving unit of a set of differential gears, the same as in an automobile, whereby the driving wheels act in conjunction with or independently of each other.

As noted in Fig. 1, Neg. 11291, by turning the steering wheel at quite an acute angle to the driving wheels, the discharge chute will remain practically stationary at the centre of the circle while the pick-up end of the extending elevator boom will travel in a circular path or by alternately reversing the propelling drive, the loader will oscillate back and forth in an arc. If the steering wheel is gradually turned through a few degrees either way from the above circular path, the whole machine, while cutting from right to left in an arc will gradually move forward into the pile, allowing full range of the machine. This illustration also shows the small radius in which the Jeffrey Radial Loader will operate.

The Radial Loader is designed to handle heavy materials such as crushed stone, sand, gravel, coal, etc. The large wheels enable it to pass over soft, rough or uneven ground, and it will rigidly maintain its equilibrium under all condi-



LOADING FROM CAR TO TRUCK.

FIG. 3—LOADING CAR FROM STORAGE PILE.

tions of ordinary rough storage ground or floor. The quickly adjustable loading boom makes the loader an ideal clean-up machine on both smooth and rough ground.

Buckets are designed for heavy service. 14-in. x 10-in. heay malleable iron buckets with renewable digger steel teeth riveted on front lips and ends protect it from wear.

The Radial Loader has a fast speed of 60 feet per minute for travelling from pile to pile, and a slow speed of 4 feet per minute for feeding into the material. Experiments have shown that a two-speed machine is absolutely essential to obtain the greatest result with the least labor.

The capacity of the Radial Loader is 1 cubic yard per minute. Will load crushed stone maximum size pieces through 2½-inch ring—maximum size coal 6-inch lumps.

The Radial Loader is equipped with either electric motor or gasoline engine. skilled labor is not required for its operation, and all controlling levers are in plain sight and in easy reach of the operator.

Fig. 2, Neg. 11400,Radial Loader handling material from storage pile to railroad car. The perfect swiveling chute makes it convenient to distribute material over a large area of car without moving the loader.

Fig. 3, Neg. 11428, leading direct from hopper bottom car into motor truck. An extra man has been placed in car to feed material through the hopper doors.

NEW PUBLICATION

In a pamphlet entitled "High Efficiency Centrifugal Pumps," the De Laval Steam Turbine Co., of Trenton, N. J., has described official tests made by the City of Minneapolis upon a 20-inch De Laval centrifugal pump driven by an induction motor, and similar tests made by the city of St. Paul upon two 12-inch De Laval centrifugal pumps driven by synchronous motors. The Minneapolis pump, which discharges 30,000,000 gal. per day against a head of 251.56 feet, showed a combined efficiency of motor and pump of approximately 82½ per cent., and a pump efficiency of 86 per cent. The smaller St. Paul units, pumping against heads up to 185 feet, showed over all efficiencies including pump and motor, of 78 and 78.4 per cent. respectively and pump efficiencies of 81.8 and 82.2 per cent. These performances, together with favorable contracts for electric power, have resulted in remarkably low costs for pumping water in each instance. This publication should be of interest to all who are concerned with the handling of water by electric power.

THE SOCIETY FOR ELECTRICAL DEVELOPMENT ENLARGE ACTIVITIES

During the war, the Society for Electrical Development was obliged to restrict its activities, although it continued throughout to do all its curtailed budget permitted, and carried on sufficiently to justify the subscriptions of those members who supported it. During the past three months so many of the big companies have resumed their membership, The General Electric Company, Westinghouse Electric & Mfg Co., Commonwealth Edison Co., Edison Electric Illuminating Co., of Boston, Consolidated Gas, Electric Light & Power Co., of Baltimore, Middle West Utilities Co., etc., that the funds available for the Society's work are over fifty per cent. greater than at the time of the November meeting of the Board of Directors.

Greater activities will be undertaken as justified by the increased revenue, and it is now desired to line up the entire industry in support of the very important work being carried on and contemplated. This work has for its main feature the education of the public to an appreciation of the uses of electricity for domestic and power purposes. No other organization is equipped to render this important service, the value of the continuation of which is far greater than the cost to the industry.

The Link-Belt Company, Chicago, have issued a leaflet descriptive of the Pratt Ballast Cleaner, which saves the work of four men in mechanically cleaning the ballast of railway tracks. The ballast is automatically excavated, screened and returned to the roadbed.

ANNOUNCEMENT

MR. F. A. COMBE, known to many readers in his former capacity of chief engineer for Canada to Babcock and Wilcox, Ltd., has severed his connection with this company, and is practising as consulting combustion and steam plant engineer with offices in the Southam Building, Montreal.

Mr. Combe's special study of problems relating to the boiler-room and his realization of the need for co-operation with operating engineers and management have determined his decision to devote his whole time to this work.

Mr. Combe was born in 1882 at Gorlestone, England, was educated at Framlingham, College; Bedford and Manchester Technical Schools, and served five years apprenticeship in the shops and drawing office of W. H. Allen, Son and Co., Ltd., Bedford. Following this training, he spent two years with the British Westinghouse Electric and Manufacturing Company on

MR. F. A. COMBE.

gas engine, erection test and outside trouble work in England, Spain and France, later returning to Messrs. Allen as chief assistant in the testing department.

Coming to Canada in 1907, he was associated for three years with various consulting engineers, having charge of the operation and remodelling of the Central Heat, Light and Power Company's plant, Montreal; Vancouver General Hospital, etc., with Messrs. Ross and Holgate; and of design and construction of the McGill University Power House, distribution systems, heating and ventilating of the McGill University Medical Building with Prof. R. J. Durley.

Since 1910, Mr. Combe has been with Messrs. Babcock and Wilcox, Ltd., during which time he has been closely connected with the majority of the large plants in Canada. Mr. Combe is a member of the Engineering Institute of Canada and also of the American Society of Mechanical Engineers.

The Operators' Point of View

NEW STYLE AND TRAP

This trap is somewhat out of the usual run of home-made affairs. I have been told that it works and gives excellent satisfaction. It is used for returning condensation from low pressure mains to a hot well, or elsewhere, by gravity.

A new point to me is the float with an open bottom. The body of the trap is made from a piece of large diameter pipe flanged top and bottom as shown, holes being drilled and threaded in the solid flanges where required.

On the end of the outlet pipe is the bottom part of an upright check valve, to disc piece of which check valve is attached a long rod a quarter of an inch in diameter. This rod should be of brass. Rests are attached to this rod at the top and at the bottom for the float to rest on.

The float is made from light sheet copper, with a copper tube soldered into the centre. The bottom of the tube is held central by four wires soldered to the tube and to the side of the float. The rod passes through this tube. The idea given me of its operation is that, as the water rises in the chamber it will gradually compress the air in the float, ultimately raising the top stop and opens the valve.

A large amount of the entrapped water will run out before the float starts to descend, thus allowing the valve to close.

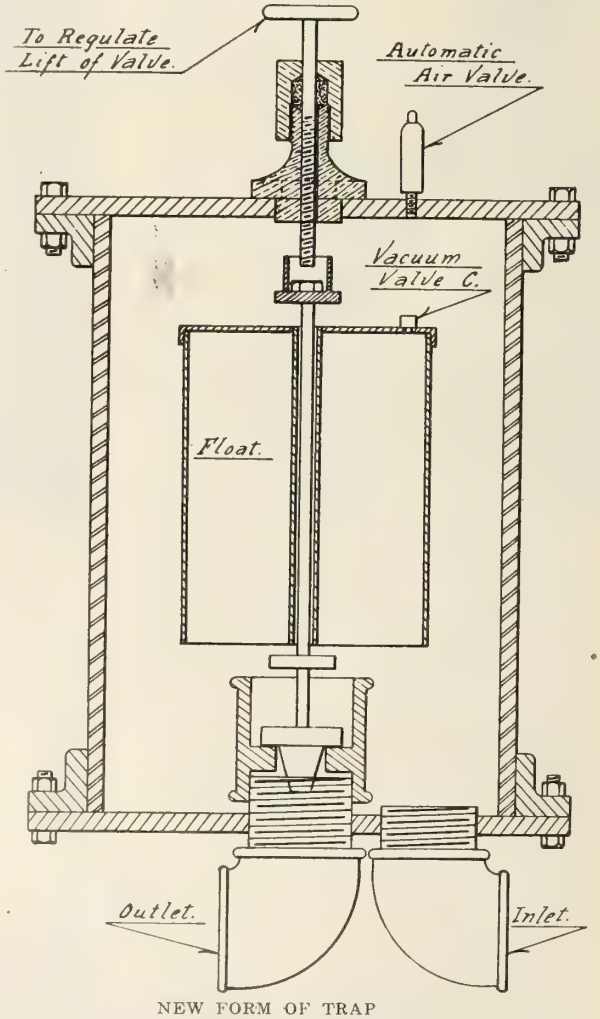
The idea is not patented and about the only thing liable to cause trouble is the small vacuum valve at C, which allows air to enter the float as the water leaves it, and closes as soon as the air reaches atmospheric pressure. However it is only a few minutes' work to remove the top flange and examine the interior of the trap at any time.

James E. Noble.

Technical Vs. Practical Skill

TECHNICAL VS. PRACTICAL SKILL

THERE have been a great many letters commenting upon the benefit and otherwise of technical and theoretical knowledge. "Get this": there is not anything to surpass it in usefulness if it is taken in proper quantities and combined with practical experience. Alone or nearly alone there is nothing more dangerous. I will tell you a true story to illustrate this fact. Mr. Blank has a university education, he also has some shop and power plant experience, not a lot. It does a fellow good to listen to him get off a fine "spiel," describing up to date power plant engineering practice. Passing for first class papers would be, and perhaps will be, pie to him, in fact, he could easily pass a superfirst examination.



NEW FORM OF TRAP

Many of your readers know gentlemen like Mr. Blank. Nice fellow and all that, just one of the boys.

One day he was standing in the engine room of a plant, the chief was also there but more distant from the engine than was Mr. Blank. Just then something went wrong with the governor and the engine started to race; the chief reached the throttle in a few half second jumps and closed it; he had to pass Mr. Blank to reach it. This gentleman only came to life after the valve was closed. Understand this, he knew perfectly well what had to be done, but not having the many years real operating experience the chief had, he could not act automatically as the chief did; he had to think before he could act; to stop to think, if only for a few seconds would have allowed time for a fly-wheel wreck.

At another time a corporation appointed a technical graduate as boiler and machinery inspector for their factories. He was a relative of the superintendent, hence the appointment. He was standing near one of the boilers telling the engineer how to do and how not to do many things. Among others he warned him to always remain cool in times of danger. This was one of the first things an engineer must learn. A man who can not remain master of himself is never to be trusted. Unless he had this control, he was not capable of teaching and controlling the rest of the engineering staff. Just at this point in the lecture, one of the high-pressure boiler safety valves let go with a bang. Mr. Inspector nearly broke his neck trying to get up the boiler room stairs without using them. Just for a few seconds he made an ass of himself. He knew perfectly well what had happened but he acted automatically up to what he was used to doing, dodging danger, not preventing it. He had not the engineer's years of personal power plant contact, so he had to think before he could realize what had happened.

The high-class technical expert is an office man; it is in the office that he can show a return in dollars and cents for the knowledge he possesses. A man must concentrate greatly to become an engineering technical expert in everything the name implies. If he does this he is bound to effect his practical experience, which enables him to do the right thing, at the right time, practically without knowingly thinking, really acting automatically.

Constant concentrated study will ad-

versely affect the practical efficiency of a mechanic. A certain amount of technical knowledge is desirable, in fact, so far as operating engineers are concerned it is indispensable.

To study up thoroughly on engine, boiler, machine, refrigerating and other machine design, requires a thorough knowledge of a dozen cults, any one or which will take a man many months to master even in a minor degree. There are exceptions but the older a person gets in manhood the more difficult it becomes to act the book student successfully.

When the average man is trying to absorb a hide full of book knowledge his mind is apt to be working independently of his body, trying to solve some problem that had bothered him the night before when he was studying up instead of sleeping. This is sure to be the very time when some dinged machine will take a notion to act contrary, and, on account of the wondering condition of his mind, the damage may be done before he can get it into its usual channel.

No operating engineer who has actual charge of a watch should concentrate overmuch on study. Take it easy, a little at a time and it will act as a tonic, not as an enervater, as much of it will surely do. This is different advice from that usually given; believe me it is the right stuff nevertheless. Of course the big fellows with a large staff of men to look after the actual operating, can study "till the cows come home," their principal work is clerical and overseeing.

Even at that, anyone who has visited many large plants will not have failed to notice the preoccupied and nervous movements of some of these big chiefs; there is too much on their minds. If they have been technical men all their business lives, having secured their practical engineering experience mainly in the office working out the financial and other power plant charts, their nervousness will be nil. Such men can not and do not understand, the love, the hate, the lure and the real dangers of the power plant. If they are men who have worked up by constant hard study and hard work they are apt to be a mass of "nerves."

I have written this article from notes taken by personal observation. Perhap I am not qualified and have formed wrong conclusions. I wonder if any other engineers have noticed things as written here.

John Ellehon.

ANNOUNCEMENT

The Mono Corporation of America, 48 Coal & Iron Exchange, Buffalo, N.Y., announce that they have purchased the entire stock of Mono apparatus and accessories from the F. D. Harger Co., Buffalo, N.Y. This includes all rights for the manufacture and sale of their various types of Mono apparatus for the automatic analysis of C02, C0, O2, H2, S02, N2, C1, etc. Mr. F. D. Harger, M.E., has not severed his connection, but will serve as general manager of the new corporation. A service and inspection department, connected with the laboratory, is now in operation and a competent chemical engineer in charge. Capable erectors will be placed at the disposal of customers in connection with the erection of new work and regular inspection trips will be arranged to visit existing installations with a view to bringing about closer co-operation between the customer and the corporation.

The Armstrong Cork Company, Pittsburg and Toronto, have issued a publication on "Small Cold Storage Rooms," which deals with the use of Nonpareil Corkboard Insulation for cold rooms in dairies, creameries, fruit and produce warehouses, retail and wholesale markets. The publication takes up engineering problems of design and pays particular attention to details of construction.

The McAlear Mfg. Co., 1901 S. Western Ave., Chicago, have issued Catalogue No. 25 and a booklet descriptive of the McAlear system of steam heating. Both of these publications deal with the apparatus and system installed by this firm and list all the equipment handled.

S. W. Craig, late of C. Cole, Ltd., has joined the Canadian Farnsworth Co. engineering staff. The Canadian Farnsworth Co. are handling the Farnsworth trap with the improved valve arrangement as developed by Mr. Rose, and are general condensation experts. Mr. Craig is well known among the engineering fraternity, who will wish him success in his new venture.

The American Steam Conveyor Corporation, Chicago, have issued a folder entitled: "A Man is Known by the Company He Keeps—A Product by Its Users." The folder shows some 50 or 60 trade marks or trade names of nationally-advertised and nationally-known concerns using the American steam jet ash conveyor

The American Steam Conveyor Carporation announce that arrangements have been made with the Wellman Bibby Company, Ltd., 36 Kingsway, London, W.C. 2, England, to act as their representative in Great Britain and Ireland for the sale of the American Steam Ash Conveyor. It is the intention of the Wellman Bibby Company to manufacture the American Steam Ash Conveyor in England.

The Jeffrey Manufacturing Company, Columbus, Ohio, is opening a branch office in Los Angeles, Cal., to look after their business in California, Arizona, Nevada, and the State of Sonora, Mexico. The office will be in charge of Mr. F. R. Field, who has been manager of the firm's Denver office, and his knowledge of this territory and of its requirements especially fit him to render assistance to clients in solving their elevating, conveying, crushing, and mining machinery problems.

STEAM TABLES—1920 EDITION

The Wheeler Condenser & Engineering Co., Carteret, N.J., announce the publication of the 1920 edition of their popular "Steam Tables for Condenser Work." This is the fifth edition. Every engineer who deals with the condensation or evaporation of steam should have one of these handy tables. The pressures below atmosphere have been especially calculated for this book by Prof. Marks.

The book gives the properties of saturated steam from 29.8 in. vacuum to atmospheric pressure in increments of tenths of an inch. The vacuum in inches of mercury is referred to a 30 in. barometer. This method is of course superior to the old method of giving absolute pressures in pounds per square inch, since it is customary to read vacuum in inches of mercury.

A complete table is also given of the properties of saturated steam above atmospheric pressure.

The book tells how to make measurements by means of the mercury column and barometer. It gives constants and tables for making corrections. It gives the correction to be made for relative expansion of mercury and brass scale, etc. It is a very handy book and of a size that can be carried in the pocket.

Officers Elected.—At a recent meeting of the stockholders of the Buffalo Forge Company, new officers were appointed, as follows: Henry W. Wendt, president; Edgar F. Wendt, vice-president and treasurer; Henry W. Wendt, Jr., vice-president and secretary; C. A. Booth, vice-president and sales manager. The new directors include the above-named officers, and, in addition, Mr. H. S. Whiting.

New Tractor Plant.—The Chase Tractors Corporation has been formed to carry on the manufacture of the Chase tractor for the Canadian market. The company will have a capital stock of $1,000,000 7 per cent. preference stock, of which $750,000 will be issued at present and $1,000,000 common stock, all of which is now issued. The company has secured a large plant adjoining the Canadian National Exhibition grounds, which will give it facilities on the main line of the Grand Trunk and C. P. R.

We are continually receiving from readers of POWER HOUSE letters telling us how much our subscribers admire the paper. We are very glad to get these letters, not so much for the purpose of reading their good words, but because they show that POWER HOUSE is meeting a real need and service in Canada. A letter of recent date says: "POWER HOUSE is very helpful to me and I would not be without it." We believe this the opinion of all our readers. The same writer says that he secures considerable valuable instruction through reading the advertising pages. The value of this is apparent to advertisers—getting the merits of their line before the engineers in an educational manner.

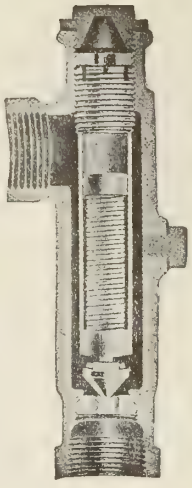
What Do You *Pay For* When You Buy a Steam Trap?



When you buy a steam trap of the cumbersome float or bucket type you **get** a lot of levers, gauges, packing, stuffing boxes and other complicated attachments. These attachments **cost money** — and you may be sure that **you** pay the bill.

It is these mechanical nuisances — that cost you **time** (for adjustment) as well as money — that make the float or bucket trap cost three times as much as

Steam Trap SARCO

The Sarco is a simple, **compact** Trap that eliminates all these mechanical extravagances. It has only one moving part and is so small that it can be placed at any point on the line in the most limited space, and at any angle. It requires no storage space, no floor space, no supports, no building up. It releases condensate almost as rapidly as it collects and sends it to the hot well while still hot — not **cold** from lying around as in the bucket traps. The lines are kept drained of **all** condensate **all** the time. Yet so promptly and accurately does the Sarco operate that no live steam is allowed to escape.

Made in sizes from ⅜" to 3" for any given pressure up to 200 lbs.

Let us ship you a Sarco for a 30 days' free trial to conclusively prove that it does everything that the three-times-more-expensive bucket trap ever did — and does it more effectively. Booklet J-7 is yours for the asking.

Two Issues per Month
Twenty-four per Year

And all for Two Dollars

There Is Only One
Plastic Fire Brick

COMES IN
THE YELLOW-TOP
BARREL

Anyone

can see that the weakest parts of a boiler lining are the joints.

The logical remedy is to have no joints—to cover all the brick work with a one-piece, monolithic furnace lining.

But the ordinary fire brick is not elastic. If you used it for this work it would crack and crumble away to dust.

The successful furnace lining is

BETSON'S
REG. U.S. TRADE MARK PLASTIC FIRE BRICK PAT. OFF.

It is the pioneer and a tried boiler refractory material. It has twenty years' practical experience behind it. It is elastic—won't crack and crumble.

There is nothing about a Betson lining to loosen or fall down. Use it in the furnace, on door arches, on rear arches, on baffles, bridge walls, etc.

Practical booklet on furnace linings sent free.

JONES

Used the World Over

UNDERFEED STOKER

Increased boiler capacity—even with low grade fuel

Are you up against the difficulty of keeping up steam with poor coal?

Or has the demand for steam exceeded the boiler capacity?

Wherever there are such conditions there is need for a Jones Underfeed Stoker.

A Jones Stoker equipment will increase the steaming capacity of your boiler and do it automatically without the close attention of the fireman and immediately show you a saving of 15 to 20 per cent. over your regular hand-fired conditions. Think of it—as much as one ton of coal saved in every five and with the price of coal where it is to-day your Jones Stoker equipment quickly pays its initial cost and then—large dividends on the investment and all the while your chimney is smokeless.

Write us for full facts.

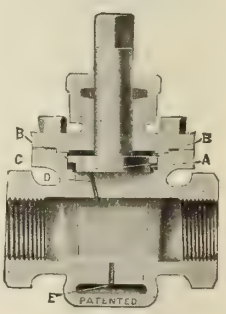
Homestead Valves

Simple and Convenient

One quarter-turn opens a HOMESTEAD QUARTER-TURN valve from absolute tightness to a straight unobstructed flow, while it takes anywhere from 6 to 10 turns of the wheel to open or close the ordinary globe or gate valve. Think of the time saved—think of the convenience—just one-quarter of a turn with a HOMESTEAD.

That's why HOMESTEADS have replaced globes and gates in hundreds of plants.

They are used for air, steam, water, oil, or acids and will keep your pipe lines absolutely tight.



HOMESTEAD VALVES are made in Straightway, Threeway and Fourway patterns.

Order your requirements to-day. Send for Catalogue.

GOODYEAR
MADE IN CANADA

INDUSTRIAL HOSE

Tires Lowered the Cost of Hose

The policy which built the Goodyear tire business—and made Goodyears the largest selling tires in the world—has made possible lower costs for hose in industrial plants.

Hose built to fit the *needs* of many different industries.

Fabrics specially selected for hose. Rubber compounds brought to an exact, scientific standard. Construction governed only by the work the hose is to do.

Is it any wonder that Goodyear Industrial Hose is giving longer service; reducing hose costs; preventing delays due to repairing and replacing hose?

In foundry, paper mill, mine, railway, steel plant, and every other industry, Goodyear is setting new standards for hose.

Goodyear Industrial Hose will open up to you new possibilities of economy, increased production and hose satisfaction.

A man trained by Goodyear in hose problems will gladly call upon you without obligation.

Just 'phone, wire or write the nearest branch.

Western Canada—Centre of Drug Smuggling

IS Western Canada the centre of the illicit drug traffic of the continent? Does the underground system, by which the body and soul-destroying narcotics are distributed to the addicts of America begin on Canadian soil?

Official U.S. investigators say so, and, in discussing the drug traffic in the March 15th issue of MACLEAN'S, Mrs. Murphy (Janey Canuck) acknowledges that there may be some truth in the statement.

In this article, the second in a series that she is writing after thorough investigation, Mrs. Murphy traces the ramifications of the underground system—how the drugs are smuggled in and purveyed to the hopeless thousands, the whole sordid story of the filching of souls and the degrading methods by which it is done.

Mrs. Murphy's articles are beginning to stir things up in Canada on the drug question. Ottawa is showing an interest, the police of many cities are displaying unusual zeal, the newspapers are awakening to the menace. Mrs. Murphy will continue her series until she has laid bare the whole truth about this danger that is gripping Canada.

Eight Months Adrift in the Arctic
By STORKER STORKERSEN

The remarkable story of how a small party of Canadian explorers, headed by the author, spent eight months adrift on ice floes in the Arctic Ocean and came back safe and sound and with a wealth of scientific data. This story has been written for and appears exclusively in MACLEAN'S.

All We Like Sheep
By NELLIE L. McCLUNG

A humorous article on a Canadian author's venture into the sheep business and what befell her.

Commerce in the Clouds
By J. VERNON McKENZIE

Pop! —never fails

THE reliability of Lunkenheimer Pop Safety Valves has been demonstrated through many years of satisfactory service, on all types of boilers.

Rigid tests under live steam and their careful adjustment to meet the individual service conditions, is assurance that they will efficiently perform the functions for which they are intended.

Their remarkable durability, due to correct design and high "quality" materials, is a source of economy in many boiler plants.

Users KNOW. A trial CONVINCES.

This is a real test.

CLINTON CEMENT

The conditions that exist in a brass furnace like this are a real test of the refractory lining. The expansion and contraction, the tremendous temperatures that occur, soon wreck the ordinary lining. The fireclay binder burns out and leaves the edges of the bricks exposed, the bricks rapidly disintegrate under the blast of flame and the lining becomes useless.

The success of Clinton Cement under these conditions is due to its unusual properties. It sets to a flexible, glass hard surface that is not affected by temperatures up to 3000° F. It is the ideal furnace lining for refractory work of any kind — but particularly the kind that gives trouble.

Five-pound tin sent free for trial.

Water-Feed Regulators
will absolutely safeguard your boilers. The VIGILANT is the pioneer automatic feed water regulator in this country, and it has remained at the zenith ever since their invention. They ensure dry steam for your engines—prevent accidents to the boilers from low water — prevent flooding of engines—lessen repairs to boilers from leaky tubes — save fuel — insure more uniform operation of feed pumps, heaters, etc.

DEPARTMENT OF LABOUR

Ontario Government

Minister: Hon. W. R. Rollo **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

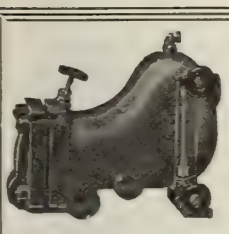
All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.



McDANIEL IMPROVED **STEAM TRAP**

FOR HIGH OR LOW PRESSURE.

Steam can't blow through. They have large discharge valves and cannot be flooded from sudden flushes of water.

MAY WE SEND ONE FOR TRIAL?

Reducing Valves, Pump Governors, Relief Valves, Exhaust Pipe Heads, Ejectors and Steam Separators.

SEND FOR CATALOGUE.

A HELPING HAND

Engineers, firemen and other power plant operators are earnestly requested to take up any matters upon which they desire information with the Editors of POWER HOUSE. This applies particularly, at the present time, to the grading of certificates in Ontario. Any new development of this kind naturally gives rise to a period of uncertainty and information is often desired by those who are most intimately concerned. We are in a very advantageous position for extending a helping hand to those in doubt as to what to do under the new regulations. Questions regarding the Act, its regulations and their interpretation, requirements for the different grades, studies to be undertaken, etc., will be cheerfully answered.

DUVAL'S METALLIC PACKING

for

ALL CLASSES OF ENGINES

and the

Highest Superheated Steam

DUVAL'S lasts for YEARS without renewal and keeps the rods in perfect condition. It is placed in the glands the same way as ordinary soft packings. Over 600,000 glands packed.

"BENHYCO" JOINTING FOR STEAM AND HYDRAULIC JOINTS. Supplied 48" square, 1/32" thick and up.

Stock carried in Montreal.

D.K.McLAREN, LIMITED · MONTREAL · TRADE MARK

THE hides used in making D. K. McLaren's Belting are cut from the *backs* of the choicest steers. The back is the strongest part—and there are equal strength and elastic qualities throughout.

D. K. McLAREN'S

Genuine British Oak Tanned

Leather Belting

THE exclusive use of selected flawless *backs* together with the world-famous British Oak method of tanning gives

D. K. McLaren Leather Belting

mighty toughness that makes for exceptionally long service.
D. K. McLaren's Belting needs but little taking-up in service because the stretch is practically all removed before shipment.

Years of strenuous service in many of Canada's largest power plants have proved D. K. McLaren's leather belting to be literally *the Belt of Greatest Reliability and Economy.*
Look for the Oak leaf. It is satisfaction insurance for you.

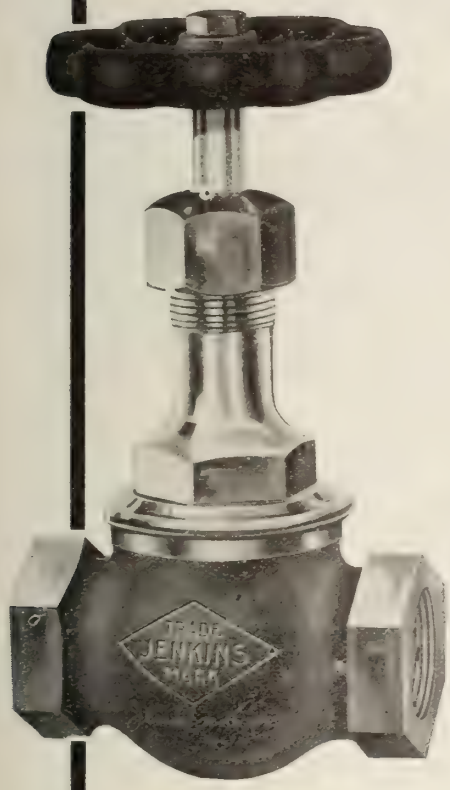
TRADE JENKINS MARK



Jenkins Bros.
Brass Globe Valve, standard pattern, Fig. 106

Dependability

— the most important feature in a valve.

The ability to withstand heavy pressures without breaking — to seat with perfect tightness under all

The certainty that there is a clear passage when the valve is open — that there is absolutely no flow when it is shut — that is dependability.

A reputation for absolute dependability has sold thousands of Jenkins Valves.

If you are a user of Brass Globe Valves and know what troubles arise from the use of ordinary makes, specify Jenkins Brass Globe Valves on your next order (see cut) and you will get the result you desire.
